INDEX

NAME INDEX

e (Ernst), (1840–1905), The Origin of a Great Optical Industry, 89
elin (Prof. I.), Thyroid Gland and Potassium Metabolism, 935
raham (E. P.) and E. Adler, Two Distinct Diaphorases, 517
am (Dr.) and Dr. Leloup, East Indian Gastropods, 229
lams (Dr. F. D.), The Birth and Development of the Geological Sciences (*Review*), 478
dison (Prof. H.), A Text-Book of Applied Hydraulics. Second edition (*Review*), 141
ller (E.), [E. P. Abraham and], Two Distinct Diaphorases, 517
riance (G. W.) and Prof. F. R. Brison, Propagation of Horticultural Plants (*Review*), 762
ir (W. O.), [T. L. Eckersley, S. Falloon, F. T. Farmer and], Wireless Propagation and the Reciprocity Law, 222
ken (Dr. A. C.), Statistical Mathematics (*Review*), 1010
bert (Prof. A. A.), Structure of Algebras (*Review*), 498
lrich (J. W.) and D. C. Nutt, Birds of Newfoundland and Colour Modification, 352
xander (Dr. R. A.), [J. H. Mason, J. D. W. A. Coles and], Cultivation of Bluetongue Virus in fertile Eggs produced on a Vitamin-deficient Diet, 1022
chin (J. P.), [Dr. J. Newton Friend and], Blue Rock-salt, 266
eo (Prof. W. C.) and Prof. A. J. Finkel, Early Development of *Arbacia punctulata*, 560
(C. W.), Photometry of the Solar D Lines, 353; lectric Potential Gradient of the Lower Atmosphere, 903
n (G. M.), Bats (*Review*), 811
n (Prof. H. S.), The α, β Transformation of Quartz, 306; and R. S. Maxwell, A Text-Book of Heat. 2 parts (*Review*), 86
sopp (Dr. C. B.), Photo-Oxides of Carcinogenic Hydrocarbons, 303
y, Fuller and Kinzer, Fluorescence of Diacetyl, 468
ton (Mrs. G.), Gift to the Royal Aeronautical Society for a Peter Alston Memorial Prize, 931
yot (Lt.-Col. J. A.), [death], 291
derson (B. W.) and C. J. Payne, Kornerupine from Ceylon: a New Occurrence, 266
lerson (P. J.), Control of Tobacco Mildew, 786
drews (H. I.), awarded the Herbert Jackson Prize of the L.M.S. Railway, 302
dross (Miss Mary), Cooking of Eggs, 789
ngerer (Prof. E.), Wissenschaftliche Photographie: Eine Einführung in Theorie und Praxis. Zweite Auflage (*Review*), 142
us (Dr. W. Rogie), Chemical Applications of Spectroscopy (*Review*), 568
rd (R.), The History of the Institution of rical Engineers (1871–1931). (*Review*), 914
r. H.), [Dr. Y. Nishina, Y. Sekido, H. Simamura , Cosmic Ray Intensities and Cyclones, 703
Dr. Agnes), The Colouring of Sixteenth-Century als, 803
(Prof. R.), Lighting of Underground Traffic lestrian Routes, 22
of. H.), Work of, 544
.), Die Entwicklung der Kontinente und ewelt, ein Beitrag zur vergleichenden hte. Zweite auflage. Band I (*Review*),
Armstrong (A. Leslie), Palæolithic Man in the North Midlands (Wilde Memorial Lecture), 78
Armstrong (Dr. E. F.), Sir Francis Goodenough, 178; Enzymes (*Review*), 204; Sir Gilbert T. Morgan, 252; Hydrocarbons (*Review*), 442; Evolution and Fats (*Review*), 839; Sir Jocelyn Thorpe, 1001
Arnold (Nicholas), [death], 653
Arrol (Dr. W. J.), Change of Ultra-Violet Transparency of Glass with Temperature, 861
Aschoff (L.), E. Küster and W. J. Schmidt, Hundert Jahre Zellforschung (*Review*), 875
Ashbridge (Sir Noel), Long-Distance Broadcasting, 194
Ashby (Dr. M.), Tung Oil, 738
Astbury (Dr. W. T.) and Florence O. Bell, Molecular Structure of the Collagen Fibres, 421
Asundi (Prof. R. K.) and Dr. B. K. Vaidya, Flame and Arc Spectra of some Calcium and Strontium Salts, 224
Atkins (O.), The Wild Dryland Blueberry (*Vaccinium vaccillans* Kalm) and Soil Conservation, 458
Attems (Dr. Graf), Myriapoda 3, Polydesmoidea II, Fam. Leptodesmidæ, Platyrhachidæ, Oxydesmidæ, Gomphodesmidæ (*Review*), 87
Attia (Rizk), Temperature of Grain Heaps, 711
Audus (L. J.), Effect of Rubbing on Leaf Respiration, 555
Aykroyd (Dr. W. R.), Nutritive Value of Rice, 522
Ayres (Prof. Q. C.) and Prof. D. Scoates, Land Drainage and Reclamation. Second edition (*Review*), 815
Azmy Pasha (S.) and A. F. Zanaty, Disease and Race, 98

Bach (S. J.), Formation of Urea, 193
Baddar (Fawzy Ghali), Benzanthrones, 822
Bagley (Dr. S. B.), elected President of the Society of Glass Technology, 666
Bagster (Prof. L. S.), [death], 964
Bailey (Dr. K.), A Crystalline Albumin Component of Skeletal Muscle, 934
Baillie (Sir James), [death], 925
Baird (Douglas Heriot), [obituary article], 133
Bairstow (Prof. L.), Applied Aerodynamics. Second edition (*Review*), 686
Baker (Sir Benjamin), Centenary of the Birth of; Work of, 505
Baker (Prof. B. B.) and Prof. E. T. Copson, The Mathematical Theory of Huygens' Principle (*Review*), 531
Balfe (W. P.), Mutarotation of Gelatin, 429
Ball (E. Bruce), Influence of the Mechanical Mind on the Development of Irrigation through the Ages, 717
Ball (Dr. J.), Geography of Egypt, 75
Ball (W. W. Rouse), Mathematical Recreations and Essays. Eleventh edition, revised by Dr. H. S. M. Coxeter (*Review*), 444
Banerjee (S.), P. B. Sen and Prof. B. C. Guha, Urinary Excretion of Combined Ascorbic Acid in Pulmonary Tuberculosis, 706
Banerji (Prof. A. C.), Development of Galactic Dynamics and some Allied Problems, 469
Banerji (Dr. S. K.), Seismological Data from India, 193
Banks (Dr. T. E.), [Dr. R. S. Krishnan and], A new type of Disintegration produced by Deuterons, 777; Fission of Uranium and Thorium under Deuteron Bombardment, 860
Banks (W. H.), [Dr. C. Ockrent and], Surface Potential Changes of Thin Films in the Transformation Liquid to Solid, 861

Bárány (E.), [Prof. J. Runnström, E. Sperber and], Cozymase in Adrenalectomized Rats, 106
Barber (D. R.), Sensitometry of Photographic Material used in Astronomy, 787
Barker (Prof. A. F.), Undercoat of the Platypus, 186
Barkley (Dr. F. A.), Keys to the Phyla of Organisms, including Keys to the orders of the Plant Kingdom (*Review*), 494
Barlee (J. S.), [Prof. H. H. Dixon and], Transpiration into a Saturated Atmosphere, 352
Barling, Bart. (Sir Gilbert), [obituary article], 735
Barnes (Dr. H. F.), The Chrysanthemum Midge, 74
Barrer (Dr. R. M.), Diffusion in Palladium, 898
Barrett (Sir James), Scope and Limitations of Physical Anthropology, 261
Barrois (Prof. Charles), [obituary article], 884
Barton (Dr. A. W.), A Text Book on Light (*Review*), 141
Bates (G. L.), [obituary article], 291
Bates (Dr. G. R.), Growth Behaviour of Plants following Seed Treatment by Organic Mercury Compounds, 262
Bates (Prof. L. F.), The Domain Theory of Magnetization (*Review*), 606; and J. C. Weston, Energy Changes Accompanying Magnetization, 188; Thermal Expansion of Invar, 550
Bawden (Dr. F. C.), Plant Viruses and Virus Diseases (*Review*), 122; Virus Research (*Review*), 483; and N. W. Pirie, Purification of Insect-transmitted Viruses, 632
Bawn (Dr. C. E. H.), The Hydrogen Bond, 846
Bayon (Dr. H. P.), Trotula and the Ladies of Salerno, 507
Beadle (D. G.), Depth of focus of Microscope Objectives, 1018
Beadnell (Surgeon Rear-Admiral C. M.), The Mass of the Universe, 549
Beare (Sir Thomas Hudson), [death], 925; [obituary article], 1002
Beck (Prof. W. A.), and R. A. Joly, A Pigmented Nucleus, 226
Becker (Prof. R.), and Dr. W. Döring, Ferromagnetismus (*Review*), 606
Beede (Prof. J. W.), [death], 542
Beijerinck (W.), Calluna: a monograph on the Scottish Heather (*Review*), 1005
Belinfante (F. J), Theory of Heavy Quanta (*Review*), 500
Bell (Florence O.), [Dr. W. T. Astbury and], Molecular Structure of the Collagen Fibres, 421
Bell (G. H.), Making of Lantern Slides, 145
van Bemmelen, Origin of Lake Toba, North Sumatra, 230
Benedicks (Prof. C.), and P. Sederholm, First Benedicks Effect in Gas-free Mercury, as Influenced by the Mean Temperature, 148, 666
Beneš (Dr. Eduard), Democracy: To-day and To-morrow (*Review*), 439
Benfield (A. E.), Heat Flow in the Earth's Crust, 230
Berenblum (I.), Dr. E. Chain and N. G. Heatley, Carbohydrate Metabolism of Tumours, 778
Bergey (D. H.), R. S. Breed, E. G. D. Murray and A. P. Hitchens, Bergey's Manual of Determinative Bacteriology: a Key for the Identification of Organisms of the class Schizomycetes. Fifth edition (*Review*), 498
Bertram (J.), [R. Maxted and], Daytime Lighting of Blacked-out Factories, 928
Besredka (Prof. A.), [death], 542; [obituary article], 617
Bessemans (Prof. A.), awarded the Jensen prize of the Paris Academy of Medicine, 66
Best (R. J.), Some Effects of Salicylate on Plant Viruses, 627
Betts (Miss A. D.), and D. Morland, Origin of the Frow Remedy for Acarine Disease of Honey Bees, 824
Beutner (Prof. R.), Life's Beginning on the Earth (*Review*), 277
Bhabha (Dr. H. J.), Classical Theory of Point Dipoles, 819
Bhâradwâja (Prof. Y.), Aspects of the Myxophyceæ, 519
Bhatnagar (Prof. S. S.), appointed director of Scientific and Industrial Research by the Government of India, 968
Białob[illegible]eski (Prof. Czeslav), [death], 19; [obituary article], 132
Bielschowsky (Prof. A.), [death], 492
Bienfait (Dr. H.), Selective Oxidation of Aluminium Alloys, 190
Biett (Dr. Laurent Théodore), centenary of the death of; work of, 342
Biggs (B. S.), [A. H. White, W. S. Bishop, S. O. Morgan and], Molecular Rotation in Organic Crystals, 596
Binns (Asa), elected president of the Institution of Mechanical Engineers, 346
Bishop (W. S.), [A. H. White, B. S. Biggs, S. O. Morgan and], Molecular Rotation in Organic Crystals, 596
Biswas (Dr. K.), The Royal Botanic Garden, Calcutta, 959
Bjerknes (Dr. J.), awarded the Symons gold medal of the Royal Meteorological Society; work of, 19
Blackadder (Prof. W.), [death], 886; [obituary article], 925
Blackett (Prof. P. M. S.), Guthrie Lecturer of the Physical Society; work of, 292; Cosmic Rays: Recent Developments (Guthrie lecture), 343
Blackwell (Sir Ernley), elected an honorary member of the Pharmaceutical Society of Great Britain, 736
Blackwood (Miss B.), Sir Hubert Murray, 453
Blair (Dr. G. W. Scott), and F. M. V. Coppen, Subjective Judgments of 'Firmness' in Elastic and Viscous Materials, 425
Blakeslee (Dr. A. F.), elected president of the American Association; work of, 341; [H. E. Warmke and], Doubling the Chromosomes of Nicotiana, 74
Blanc (A. C.), Fossil Man of Monte Circeo, Italy, 631
Blank (F.), [Prof. A. Frey-Wyssling and], Growth of Protoplasm and Nitrogen Migration in the coleoptile of *Zea Mays*, 974
Blanshard (Prof. B.), The Nature of Thought. 2 vols. (*Review*), 798
Blaschko (Dr. H.), Amine Oxidase and Benzedrine, 26
Bleek (Miss Dorothea F.), More Rock-Paintings in South Africa: from the Coastal Belt between Albany and Piquetberg. Mainly copied by Joyce and Mollie van der Riet (*Review*), 992
Blumenbach (Johann Friedrich), centenary of the death of; work of, 63
Blyton (W. J.), Brave New World Planning, 966
Boas (Prof. F.), Race, Language and Culture (*Review*), 951
Bonacina (L. C. W.), Landscape Meteorology and its Reflection in Art and Literature, 22; Snowfall in the Winter of 1939–40, 554
Bonhoff (Prof. H.), [death], 618
Bonner (J.), [J. English, A. J. Haagen-Smit and], Wound Hormones of Plants, 353
Booth (F.), [A. H. Wilson and], Large Cosmic Ray Showers and Mesons, 103
Booth (H. S.), and F. C. Mericola, Thionyl Chlorofluoride, 786
Børgesen (F.), Algæ from the Iranian Gulf, 674
Bork (Prof. W. F.), [death], 1011
Born (Prof. Max), Aspects of Theoretical Physics (*Review*), 528; Prof. Otto Toeplitz, 617; Relation between Breaking and Melting, 741; and K. Fuchs, The Mass Centre in Relativity, 587; 933
Borst (Prof. Max), awarded the Goethe medal for and Science, 146
Bosch (Dr. C.), [death], 695
Bose (Prof. D. M.), and Miss Biva Chowdhry, Ph graphic Plates as Detectors of Mesotron Show 894
Bose (Prof. S. R.), Moisture-relation as a det factor in the transformation of the Basidia Polyporaceæ, 706; Effect of Inversion of piece from the Fruit-body of *Ganoderma* (Leyss.) Karst. growing *in situ* on the *Casuarina equisetifolia*, 899
Bottomley (A. C.), and Dr. S. J. Folley, Ina Prolactin by treatment with Phenyl *Is*
Boulenger (Prof. C. L.), [death], 805; [ob 962
Bowie (R. M.), [R. S. Morse and], A Gauge, 712

TITLE INDEX

Abbe, Ernst (1840–1905): The Origin of a great Optical Industry, 89
Aberdeen University: conferment of honorary doctorates on Sir William Jameson and Prof. F. A. Lindemann, 599; impending retirement of Prof. A. Findlay; appointment of Dr. H. W. Melville as professor of chemistry in, 654
Absolutkolorimetrie, Prof. A. Thiel (*Review*), 141
Acadian French in Louisiana, H. N. Gould, 555
Acetaldehyde: High Temperature Photolysis of, G. K. Rollefson and D. C. Grahame, 712; Photolysis of, C. J. Danby, 940
Acetylcholine: Liberation of Potassium from Muscle by, V. H. Cicardo and J. A. Moglia, 551; Vitamin B_1 and, formation in Isolated Brain, Dr. P. J. G. Mann and Dr. J. H. Quastel, 856
Acetylcholinesterase, Action of Ions on, L. Massart and R. Dufait; Prof. B. Mendel, Dorothy Mundell and Frida Strelitz, 822
Acetyl Content of Marinobufagin, Arenobufagin and Acetylmarinobufagin, Dr. V. Deulofeu, E. Duprat and R. Labriola, 671
Achromatic Lens, Drs. N. V. E. Nordenmark and J. Nordstrom, 344
Acids, Weak, Ionization Constants of, B. Saxton and L. S. Darken, 979
Acoustic Generator, An, Prof. Hartmann, Peter and Elisabeth Mathes and F. Lazarus, 787
Acoustics, Applied, Dr. H. F. Olson and F. Massa. Second edition (*Review*), 138
Adaptive Coloration in Animals, Dr. H. B. Cott, 949
Administration, Scientific Management in, 275
Adrenal Cortex, The Function of the, Dr. W. Feldberg (*Review*), 404
Advertising, [1870], 984
Aerial, Geological and Geophysical Survey of Northern Australia, Dr. L. Dudley Stamp, 433
Aerodynamics: Practical, Elements of, Prof. Bradley Jones. Second edition (*Review*), 496; Applied. Second edition, Prof. L. Bairstow; Prof. L. M. Milne-Thomson (*Review*), 686
African: Studies: and the War, 180; International Co-operation and, 180; Native Institutions and Christianity, Prof. N. de Cleene, 181; Studies in War-time Paris, 928
Agarics, New Descriptions of, A. A. Pearson, 153
Agrarian Affairs, International Journal of, No. 1, 145
Agricultural Work for University Students, 854
Agriculture: British, The place of Science in, Dr. E. H. Tripp (*Review*), 366; in the Twentieth Century: Essays on Research, Practice and Organization to be presented to Sir Daniel Hall (*Review*), 366; A Text-book of, designed for use in East African Schools, J. G. Brash (*Review*), 1003
Air: Currents, Vertical, K. P. Ramakrishnan, 75; Transport, Insects and Disease, F. G. Sarel Whitfield; Dr. A. D. Imms, 76; Conditioning, W. Chambers, 270; Transport, Insects and Disease, Dr. F. P. Mackie, 391
Aircraft: Design in (*Review*), 368; Design. Vol. 1: Aerodynamics; Vol. 2: Aerostructures, C. H. Latimer (*Review*), 368; Long-Range, Development of, 539; Production, Minister of, Sir Frank E. Smith appointed controller of telecommunications by the, 931
Akiga's Story: The Tiv Tribe as seen by One of its Members. Translated and annotated by Dr. R. East (*Review*), 655
Alchemical Manuscripts, 65
Alcohol: Effects of, on the Human Body, [1870], 869; and Mental Disease, H. M. Pollock, 902
Aldehydes, Gattermann Synthesis of, A. G. Mistretta and Prof. F. F. Nord, 387
Algæ from the Iranian Gulf, F. Børgesen, 674
Algebra for Science and Engineering Students, E. H. Lockwood (*Review*), 1008
Algebras, Structure of, Prof. A. A. Albert (*Review*), 498
Algeria, Southern, Populations of, Dr. M. Gronier, 1013
Alien Scientific Workers, Internment of, 796
Alkali and Alkaline Earth Metals exposed to Air, An Electron Diffraction Study of the surfaces of, S. Yamaguchi, 742
Allegheny Plateau, Erosion Surfaces in the, J. L. Rich, 431
Allium, Cytological Investigations in, S. W. Mensinkai, 353
Allomyces, Life-cycle of, R. Emerson, 1025
Altazimuth Mounting for Reflecting Telescopes, Rev. W. Rees Wright, 353
Aluminium Alloys, Selective Oxidation of, Dr. H. Bienfait, 190
Amaryllidaceæ, Taxonomy in the, 774
American: Psychologists in War-time, 21; Universities and Colleges, 1939, Statistics of Registration in, 259; Vegetables (*Review*), 283; Association: Columbus Meeting, Dr. F. R. Moulton, 288; Dr. A. F. Blakeslee elected president of the, 341; Archæology, Methods and Aims in, 437; Cities and States, Studies of, E. L. Thorndike, 467; Archæology and Local Research, 546; 558; Investigations in Embryology, Recent, Prof. R. W. Sperry; Profs. W. C. Allee and A. J. Finkel, Miss Ethel Browne Harvey; Prof. R. and E. L. Chambers; Prof. H. L. Eastick, 560; Ethnology, Bureau of, Fifty-sixth annual report, 1938–39, 773; Association of Anatomists, Prof. Philip E. Smith elected president of the, 776; Scientific Congress, The Eighth, Dr. Austin H. Clark, 918
American Weekly, R. D. Potter appointed science editor of the, 968
Amerindian Portraiture, Pioneers in, 255
Amine Oxidase and Benzedrine, Dr. H. Blaschko, 26
Amino-Acids: in Protein Digests, Separation of, R. L. M. Synge, 309; of Casein, Phosphopeptone, Dr. M. Damodaran and B. V. Ramachandran, 857
Ammocharis, Leaf-growth as a Systematic Feature in, Milne-Redhead and Schweickerdt, 229
Amœba lescheri (=*Chaos lescheri*): a New Species of Amœba, Dr. Monica Taylor and Sister Catherine Hayes, 464
Amphibian Anatomy, L. S. Ramaswami, 467
Amphipod Bathyporeia in Tow-nettings, E. E. Watkin, 711
Amphipods, off-shore, in the Littoral Zone, Occurrence of some, C. B. Goodhart and R. Harrison, 109
Anærobic Bacteria, The, and their Activities in Nature and Disease: a Subject Bibliography, Elizabeth McCoy and L. S. McClung. 2 Vols. (*Review*), 499
Anaspid, A New, from the Upper Devonian of Scaumenac Bay in Canada, with remarks on the other Anaspids, E. A:Son Stensiö, 674
Angami Nagas, Blood Groups of the, Dr. S. S. Sarkar, 261
Anglo-French Co-operation in Schools, 565

Anglo-Soviet Journal, No. 1, 301
Anilides, Hydration of, of Normal Fatty Acids, B. A. Toms, 1019
Animal: Viruses, Electrophoresis of, and their Neutralizing Antibodies in Low Concentrations, Dr. A. Polson, 27; Development, Organisers in, 98; Specimens, Temporary Preservation of, Dr. P. Chabanaud, 397; Biology, Practical, T. L. Green (*Review*), 656
Annuaire pour l'an 1940, Publié par le Bureau des Longitudes. Avec des Notices scientifiques (*Review*), 498
Annual Register, 1939. Edited by Dr. M. Epstein (*Review*), 1009
Anomura, Japanese, G. Melin, 785
Anopheles subpictus, Influence of Spermathecal Stimulation on the Physiological Activities of, Dr. D. N. Roy, 747
Antelope (*Antilope cervicapra*), Upper Canine Teeth in the Indian, Prof. J. Ritchie, 859
Anthropological Nomenclature, Prof. W. C. Osman Hill, 260
Anthropology, Physical, Scope and Limitations of, Sir James Barrett, 261
Anthropomorphic Pottery, Facial Deformity in, R. N. Salaman, 309
Antiquaries, Society of, award of the gold medal of the, to Prof. A. M. Tallgren, 582
Antiquity: a Sutton Hoo number, 585
Antirrhinum, Incompatibility in, Marta Sharman, 675
Anura, Lymphatic System of the, Dr. H. M. Knower, 755
Appetite, Excessive and Depraved, [1870], 869
Apple Trees, Water Culture of, H. L. Pearce, 595
Aquaria Societies, Difficulties of, 21
Arabe, La science, et son rôle dans l'évolution scientifique mondiale, A. Mieli. Avec quelques additions de Henri-Paul-Joseph Renard, M. Meyerhof and J. Ruska (*Review*), 4
Archæological Discoveries of 1939 in Ireland, 21
Archæology: in the U.S.S.R., Prof. V. Gordon Childe, 110; the Writer of the Note, 111; American: Methods and Aims in, 437; Recent Researches in, 558
Architecture, History of, Outlines of the, Part 4: Modern Architecture, with particular reference to the United States, Prof. R. Newcomb (*Review*), 297
Aristapedia, Development of, W. Braun, 902
Aristotelian Logic, The Structure of, Prof. J. W. Miller (*Review*), 815
Armed Forces, Education in the, 526
Army, Health of the, 968
Aromatic Molecules, Diamagnetism of the Mobile Electrons in, Prof. K. S. Krishnan, 470
Astronomy: W. T. Skilling and R. S. Richardson (*Review*), 445; General, Dr. W. H. Steavenson (*Review*), 445
Atlas of Britain, A National, Prof. E. G. R. Taylor, 487
Atmosphäre, Physik der, Herausgegeben von V. Conrad. Bearbeitet von J. Zenneck, R. Steinmaurer, P. Gruner, H. Landsberg and F. W. P. Götz (*Review*), 760
Atmospheric: Disturbances, Microseisms and Transmission of, K. Sezawa and K. Kanai, 154; Pollution, Investigation of, Conference on, Prof. W. H. Roberts elected chairman of the, 929
Atmospherics, Study of, Prof. T. H. Laby, J. J. McNeill, F. G. Nicholls and A. F. B. Nickson, 517
Atombau und Spektrallinien, Prof. A. Sommerfeld. Band 2. Zweite Auflage (*Review*), 528
Atomic: Constants, Evaluating, A Simple Rule for, Prof. Po-leon Woo, 30; Clocks, Measurement of Velocity with, Dr. H. E. Ives, 417; Oxygen, Cross-section of, for Elastic Collision with Electrons, and Region *F* Absorption, Prof. S. K. Mitra, Benoy B. Ray and S. P. Ghosh, 1017
Atoms, Size of, [1870], 523
Audiphone Measurements, An Artificial Mastoid for, M. S. Hawley, 258
Aurora and Magnetic Storm of March 24–25, Rev. J. P. Rowland, 625
Australia: and New Zealand, Electricity Supply in, 77; Setting-up of a Central Medical Co-Administrative Committee in, 420; Northern, Aerial, Geological and Geophysical Survey of, Dr. L. Dudley Stamp, 433; Census of Aboriginals in, 586; Migration to, in 1939, 666; Chemical Research in, 700
Australian: Aborigines, Scaphocephaly among, F. J. Fenner, 74; Shell Ornaments, C. P. Mountford and A. Harvey, 74; Aboriginal Artist, An, E. P. Goddard, 699; Mud-fish, New, [1870], 908; -New Zealand Cancer Conference, Tenth, 930; Aborigines, Plant Foods of, Mrs. I. W. Dadswell, 966
Austrian Academy in Great Britain, Foundation of an, 664
Axolotl Larva, Diurnal Rhythms in the, and in Drosophila, Dr. H. Kalmus, 72
Azomethane, Decomposition of, Henkin and H. A. Taylor, 431

β-Ray Absorption, A Photographic Method of Studying, by $^{32}_{15}$P, Dr. J. Govaerts, 624
Bacon, Curing of, Function of Nitrate, Nitrite, and Bacteria in the, 817
Bacterial Warfare, [1870], 523
Bacteriological Warfare, Dr. E. Sarfati, 621
Bacteriology: for Medical Students and Practitioners, Prof. A. D. Gardner (*Review*), 293; Fundamental Principles of, with Laboratory Exercises, Prof. A. J. Salle (*Review*), 659
Bacteriophage: and Plant Lysins, R. C. Thomas, 468; C_{16}, Effect of Radiations on, E. Wollman, F. Holweck, and Dr. S. Luria, 935
Bantu Lexicography, Rev. C. M. Doke, 192
Barkhausen-Kurz Oscillations with Positive Ions, W. S. Elliott and J. A. Ratcliffe, 265
Barley: Malting, H. V. Garner and J. W. Weil, 738; Linkage Studies in, D. W. Robertson and O. H. Coleman, 827
Barolong, South Africa, Marriage Customs among the, Z. K. Matthews, 268
Basidia of certain Polyporaceæ, Moisture-relation as a Determining Factor in the Transformation of the, Prof. S. R. Bose, 706
Bats, G. M. Allen (*Review*), 811
Battery Vehicle, Development of the, J. H. Cansdale, 457
Bean: Rust Fungus, Control of the, Dr. A. F. El-Helaly, 75; Seed Coat Colour in the, H. A. K. Lamprecht, 827
Bees, The Mind of the, J. Françon, translated by H. Eltringham (*Review*), 298
Begin Here: a War-time Essay, Miss Dorothy L. Sayers (*Review*), 815
Belgian: Cretaceous, Fauna of the, Dr. R. Marlière, 942; Lower Devonian, Flora of the, F. Stockmans, 942
Benedicks Effect in Gas-free Mercury, First, as influenced by the Mean Temperature, Prof. C. Benedicks and P. Sederholm, 148, 666
Benzanthrones, Fawzy Ghali Baddar, 822
Benzedrine, Amine Oxidase and, Dr. H. Blaschko, 26
3 : 4-Benzpyrene: Paramecium and the Production of Tumours, J. C. Mottram, 184; Photodynamic Hæmolysis by, I. Doniach and J. C. Mottram, 748; Some Physico-Chemical Properties of, Prof. F. Weigert and J. C. Mottram, 895
Bergey's Manual of Determinative Bacteriology: a Key for the Identification of Organisms of the class Schizomycetes, D. H. Bergey, R. S. Breed, E. G. D. Murray and A. P. Hitchens. Fifth edition (*Review*), 498
Bermuda Seismograph Station, 739
Bilirubin in Urine, Dr. F. Marsh, 782
Binocular Vision, Sir John Graham Kerr, 901
Biochemistry: Annual Review of, Editor, J. M. Luck; Associate Editor, J. H. C. Smith (*Review*), 369; Progress in (*Review*), 369
Biography in the U.S.S.R., Dr. B. P. Uvarov (*Review*), 52
Biological Films, Some New, 890; Objects, Total Energy Absorption in, Dr. W. V. Mayneord, 972

Biology: A School Course of, with suggestions for Practical and Field Work, L. J. F. Brimble (*Review*), 205; for Junior Forms: with instructions for Simple Practical Experiments, M. R. Lambert (*Review*), 205; for Schools, T. H. Hawkins (*Review*), 205; in Schools, 384; Textbook of, Dr. E. R. and A. V. Spratt. Second edition (*Review*), 810

Bird: Behaviour, The Releaser Concept in, D. Lack, 107; Migration and Gonad Development, A. Wolfson, 826; Life, Intimate Sketches from, E. J. Hosking and C. W. Newberry (*Review*), 874; Portraits, Seton Gordon (*Review*), 874

Birds: of Newfoundland and Colour Modification, J. W. Aldrich and D. C. Nutt, 352; of Prey, Wild, Age of, E. L. Sumner, jun., 430

Birmingham University: War conditions in, 20; Progress of, 383; Dr. C. Dannatt appointed professor of electrical engineering, 1013

Birth-rate in Chief Capitals, Annual, 666

Bismuth, Nuclear Reactions with, D. G. Hurst, R. Latham and W. B. Lewis, 633

Bismuthinite in Somerset, Occurrence of, A. W. G. Kingsbury, 351

Bleeding, Control of, Preparation for the, 384

Blind: Spot of Mariotte, The, Dr. J. Bröns, 383; Cave Fish, Eye of a, E. B. Gresser and C. M. Breder, jun., 1025

Blood: Circulation of the, Prof. J. H. Gaddum (*Review*), 206; Circulation of the, The Control of the, Prof. R. J. S. McDowall, with the assistance of Lt.-Col. G. E. Malcomson and I. McWhan (*Review*), 206; Groups of the Angami Nagas, Dr. S. S. Sarkar, 261; Groups and Racial Diagnosis, G. L. Taylor, R. R. Race, Aileen M. Prior and Elizabeth W. Ikin, 415; -group Tests and Paternity, Dr. D. Harley and Dr. G. R. Lynch, 889; -groups and Castes, D. N. Majundar, 1025

Bluetongue Virus in Fertile Eggs produced on a Vitamin-deficient Diet, Cultivation of, J. H. Mason, J. D. W. A. Coles and Dr. R. A. Alexander, 1022

Boas, Prof. Franz (*Review*), 951

Boiler: Feed Water Treatment, F. J. Matthews. Second edition (*Review*), 840; Water Treatment (*Review*), 840

Bombay, Control of Spirit in, 420

Bond Angle Distortion, A Magnetic Study of the Effect of, D. P. Mellor and W. H. Lockwood, 862

Books in War-time, 719; A. Marshall, 977; 1013

Boron: Monobromide, Band Spectrum of, Rotational Analysis of the, Dr. E. Miescher and E. Rosenthaler, 624; in Agricultural and Horticultural Practice, 766

Bose-Einstein or Fermi-Dirac Statistics? Does the Mesotron Obey, P. L. Kapur, 69

Botany, Early, at Oxford, Dr. J. Ramsbottom, 993

Bow, The Constellation of the, Sirius and, Dr. H. Chatley, 670

Boyle and Wren, Friendship of, Ruth Musser and J. C. Krantz, jun., 182

Brain: Tissue, 'Coupling' of Phosphorylation with Oxidation of Pyruvic Acid in, Dr. S. Ochoa, 747; Intellect and Size of, [1870], 793; Isolated, Vitamin B_1 and Acetylcholine Formation in, Dr. P. J. G. Mann and Dr. J. H. Quastel, 856

(*Brassica campestris* L.), An Apetalous Mutation in Turnip, Dr. S. Ramanujam, 552

Breaking and Melting, Relation between, Prof. R. Fürth; Prof. Max Born, 741

Britain, A National Atlas of, Prof. E. G. R. Taylor, 487

British: Association, the War and the, 61; and American Civil Engineers, 97; Museum (Natural History), Acquisitions of the, 181; Pharmacopœia: Proposed Innovations, 196; Empire Cancer Campaign, The, Dr. E. Boyland, 246; Empire, Mineral Resources of the, 258; India, including Ceylon and Burma, The Fauna of, Butterflies, G. Talbot. Vol. 1 (*Review*), 293; Museum (Natural History), Exhibition of Animals and Plants of use to Man, 300; Opening hours of the; acquisitions, 346; Museum, Annual Report for 1938, 383; East Africa, Meteorology in, A. Walter, 418; Museum (Natural History), Exhibits in the, 506; Association, Arrangements for the 1940 meeting of the, 619; Museum (Natural History), recent acquisitions, 698; Empire Naturalists' Association, retirement of Mrs. G. B. Thomason, 739; Museum, Sir Robert Mond bequest to the, 774; Museum (Natural History), presentation of specimens of Bravoite to the, 854; Pharmacopœia: Emergency Monographs, 889; Association, cancellation of the 1940 Conference, 892; Pharmaceutical Conference, chairman's address of H. Humphreys Jones, 927

Broadcasting: Long-distance, Sir Noel Ashbridge, 194; over Wires, Dr. T. Walmsley, 434

Bronzes from Southern Nigeria, J. O. Field, 352

Browne, Buckston, prize, award of the, to Capt. R. Kemp, 183

Bruce, Dr. W. S., Memorial Prize award of the, to Brian Roberts, 931

Bryophyta, Spores of, Miss Knox, 978

Buddha, Relics of the, 343

Bulletin Analytique, the, 965

Burrell Engines, Some early, R. H. Clark, 345

Byrd Antarctic Expeditions, 1928–30 and 1933–35, Meteorology of the, C. Grimminger and W. C. Haines, 34

Cabbage White Butterflies, Destruction of, by Birds, Prof. G. D. Hale Carpenter, 900

Calcium Phytate, Ionization of, E. F. Yang; Prof. D. C. Harrison and Sir Edward Mellanby, 745

Calculus, An Introduction to the, Prof. K. R. Gungikar (*Review*), 812; Advanced, Prof. I. S. Sokolnikoff (*Review*), 1008

California University, Grant from the Rockefeller Foundation for a Cyclotron, 776

Calluna: a Monograph on the Scotch Heather. W. Beijerinck (*Review*), 1005

Cambridge: University: Prof. A. V. Hill elected a parliamentary representative of, 341; Natural Science at, [1870], 561; Dr. W. L. H. Duckworth elected Master of Jesus College, 888

Camouflage in Modern Warfare, 949

Canada: Demography of, Dr. H. B. Jeffs, 24; National Research Council of, Awards, 740; Conservation in, A. F. Coventry, 967

Canada's Indian Policy, D. Jenness, 773

Canadian: Mineral Industry in 1938, 700; Polar Year Expeditions, 1932–33, 774

Cancer: Campaign, The British Empire, Dr. E. Boyland, 246; Interferometric Serum Test for, Dr. M. W. Mettenleiter, 305; the role of Surgery, Radium and X-rays in its Treatment, 321; -producing Chemical Compounds, Prof. J. W. Cook, 335; Cell and Growth-regulating System of the Body, Prof. L. Doljanski and Dr. R. S. Hoffman, 857; Conference, Australian-New Zealand, Tenth, 930

Cannabidiol and Cannabol, Constituents of *Cannabis indica* Resin, A. Jacob and Prof. A. R. Todd, 350

Cannabis indica Resin, Cannabidiol and Cannabol, constituents of, A. Jacob and Prof. A. R. Todd, 350

Cannabol, Cannabidiol and, Constituents of *Cannabis indica* Resin, A. Jacob and Prof. A. R. Todd, 350

Canoe-making in Ancient Hawaii, Translated and edited by K. P. Emory and Mary Pukui, 352

Caranx, Young, in the Western North Atlantic, J. T. Nichols, 632

Carbohydrate Manuring, Prof. N. R. Dhar, 632

Carbon: Monoxide as a hazard of Polar Exploration, Prof. Yandell Henderson and J. McCullough Turner, 92; Dioxide in Arctic and Antarctic Seas, Dr. G. E. R. Deacon, 250

Carboxylase System, Cause of the 'Activation' of the, by Free Aneurin, Dr. H. G. K. Westenbrink, and Dr. D. A. van Dorp, 465

Carboxypeptidase, Effect of X-Rays on, W. M. Dale, 977

Carcinogenesis, Cytology of, Dr. Pullinger, 8[illegible]4

Carcinogenic: Hydrocarbons, Photo-Oxides of, Dr. C. B. Allsopp, 303; Colouring Matters, H. S. Redgrove; Prof. J. W. Cook, 672; Action, Substances which Modify, Dr. Crabtree, 785
Carica Papaya, Genetical Studies in, J. D. J. Hofmeyer, 902
Carnegie Trust for the Universities of Scotland, Report of the, 700
Carotene and Allied Pigments, Dr. R. A. Morton; W. M. Seaber, 286
Carrageen Mucilage, Acetolysis of, Prof. T. Dillon and P. O'Colla, 749; Dr. E. G. V. Percival and J. Buchanan, 1020
Casein Phosphopeptone, Amino-Acids of, Dr. M. Damodaran and B. V. Ramachandran, 857
Catalysis, Mechanism of, by Enzymes, D. B. Taylor, 423
Cat Fish, Melanophores of the, G. H. Parker, 555
Catlin and his North American Indian Gallery and Museum, L. J. P. Gaskin, 158
Causality and Science, Prof. N. K. Brahma (*Review*), 1009
Cave: Faunas, 234; Man in Colorado, 384
Cell Theory, The, A. Glücksmann (*Review*), 875
Cellular and Comparative Physiology, Journal of, Dr. D. W. Bronk appointed editor of the, 740
Cellulose: Sheet: Anisotropy of, D. G. Drummond, 67; Optical Anisotropy of, Dr. R. C. Gray, 266; Acetate, Structure of, Dr. C. A. Redfarn, 515; Sheets, Optical Anisotropy of, Dr. J. Spence, 515
Central European Observer, 258
Central Register of Specialists (Section for Scientific Research), 176
Centromere, Irregular Division of the, Dr. C. D. Darlington, 942
Ceratium, Distribution of, E. S. Nielsen, 33
Cereals for Spring Sowing, Varieties of, 183
Cerebro-Spinal Fever, Memorandum on, 586
Chalcoponera metallica, Economic Importance of the Australian Ant, H. B. Fell, 707
Chalk Landscape, Lord Kennet of the Dene, 466; C. J. P. Cave, 629
Channel: Railways: Projected, [1870], 118; 637; Islands, The Archæology of the, Vol. 2: The Bailiwick of Jersey, Mrs. Jacquetta Hawkes (*Review*), 684
Charity and the Struggle for Existence, Dr. R. R. Marett (Huxley Memorial Lecture), 37
Chaulmoogra Oils, H. I. Cole and H. T. Cardoso, 310
Chemical: A Use for Every (*Review*), 7; Industries, The Economics of, Dr. E. H. Hempel (*Review*), 137; Society, New departure of the, [1870], 160; Industry, Society of, Lord Samuel awarded the Messel medal of the, 509; Bond, The, Prof. C. K. Ingold (*Review*), 644; Bond, The Nature of the, and the Structure of Molecules and Crystals: an Introduction to Modern Structural Chemistry, Prof. L. Pauling (*Review*), 644; Engineering, Applied Mathematics in, Prof. T. K. Sherwood and Prof. C. E. Reed (*Review*), 658; Society, Advisory Research Council of the, Activities of the, 771
Chemicals and Related Materials, Uses and Applications of, compiled and edited by T. C. Gregory (*Review*), 7
Chemie: Organischen, Ausführliches Lehrbuch der, Prof. W. Schlenk. Band 2 (*Review*), 202; physikalischen, Kurzes Lehrbuch der, Prof. K. Jellinek. Heft 1 u. 2 (*Review*), 281; analytischen, Physikalischen methoden der, herausgegeben von W. Bottger. Teil 3 (*Review*), 495
Chemisch Weekblad, Retirement of Prof. W. P. Jorissen from the editorship of the, 20
Chemistry: for Intermediate Examinations, Dr. J. N. Sugden (*Review*), 51; General and Inorganic, Dr. P. J. Durrant (*Review*), 51; Inorganic, A College Course of, Prof. J. R. Partington (*Review*), 51; Intermediate, Inorganic and Physical, Dr. F. Prescott (*Review*), 51; Youth on the Prow in, Prof. J. Read (*Review*), 123; Organic, Aids to, Stanley F. Smith (*Review*), 137; of Organic Compounds, Sir Jocelyn Thorpe (*Review*), 202; of Organic Compounds: The, a Year's Course in Organic Chemistry, Prof. J. B. Conant, revised with the assistance of Dr. Max Tishler (*Review*), 202; Organic, Practical, Introduction to, Dr. F. G. Mann and Dr. B. C. Saunders (*Review*), 202; Physical, A course of (*Review*), 281; A History of, Dr. F. J. Moore, revision prepared by Prof. W. T. Hall. Third edition (*Review*), 294; Inorganic, F. Ephraim. Third English edition, by Dr. P. C. L. Thorne and Dr. A. M. Ward (*Review*), 294; Institute of, work of the, Sir Robert Pickard; Dr. J. J. Fox elected president, 382; in Forestry, Role of, Dr. S. Krishna, 470; Organic, Perkin and Kipping's, Prof. F. Stanley Kipping and Dr. F. Barry Kipping. Part 3. Revised edition (*Review*), 495; Inorganic, Laboratory Exercises in, Prof. J. F. Norris and Prof. K. L. Mark. Second edition (*Review*), 657
Chemists: Young, and great Discoveries, Prof. J. Kendall (*Review*), 123; Analytical, Activities of, Prof. W. H. Roberts, 416
Chiasmata, Position of, K. Mather, 979
Child Development: Biographies of, the Mental Growth Careers of Eighty-four Infants and Children; a Ten-year Study from the Clinic of Child Development at Yale University. Part 1, Dr. A. Gesall; Part 2, Dr. Catherine S. Amatruda, Dr. B. M. Castner and Dr. Helen Thompson (*Review*), 140
Chimie Mathématique, La, Prof. T. De Donder. Vol. 1 (*Review*), 528
Chimpanzees, Observation of, Prof. R. M. Yerkes, 890
China: South, Hygiene in, Inspector-Genl. Dr. A. Lasnet, 100; Geological Research in, Dr. J. Coggin Brown (*Review*), 169; The Geology of, Prof. J. S. Lee (*Review*), 169; Northern, Fruit Flies of, Y. Zia and Sicien H. Chen, 595; Early Man in, Bone and Stone Industries of, 904; Mycology in, S. C. Teng and S. H. Ou; S. C. Teng and K. L. Teng, 1025
Chinese Art, Exhibition of, at Leeds, 509
Chloroacetic Acids, Resonance in the, H. O. Jenkins, 625
Chlorocruorin in Sabella, Function of, and of Hæmoglobin in Lumbricus, Prof. H. Munro Fox, 781
Choline Esterase, Action of Ions on, Dr. D. Nachmansohn, 513
Choukoutien: Sinanthropus Site, Bone and Antler Industry of the, Dr. H. Breuil, translated by Miss M. E. Boyle, 904; The Upper Cave Industry of, Pei Wen Chung, 904
Christianity Survive?, Can, Rev. Dr. M. Davidson (*Review*), 329
Chromosome Numbers of British Plants, P. Maude, 865
Chrysanthemum Midge, Dr. H. F. Barnes, 74
Ciel, Exploration du, P. Rousseau (*Review*), 445
Cimex, Sex-chromosomes in, Dr. C. D. Darlington, 113
Cinchona production in the Netherlands Indies, Dr. M. Kerbosch, 738
Cinematography, Colour, Major A. B. Klein. Second edition (*Review*), 142
Circuit-Breakers, Miniature, 548
Circumlocution, [1870], 946
Cirque Formation, W. V. Lewis, 269
Civil: Defence: a Practical Manual presenting with working drawings the methods required for Adequate Protection against Aerial Attack, Capt. C. W. Glover. Second edition (*Review*), 661; Engineers, Institution of, award of the James Alfred Ewing medal to Prof. G. I. Taylor, 852
Civilization and the Rights of Man, 237
Clocks, Electric, Sir Charles Vernon Boys (*Review*), 326
Coal, Deep Mining for, [1870], 198
Coelom, Vertebrate, Origin of the, H. B. Fell, 906
Cognition, Non-Sensory, Experiments in, W. W. Carington and S. G. Soal, 389
Cold, Catching, [1870], 198
Coleoptera, British, Larvæ of, Dr. F. van Emden, 74
Collagen Fibres, Molecular Structure of the, Dr. W. T. Astbury and Florence O. Bell, 421
Collectif, notion de, Étude critique de la, Prof. J. Ville (*Review*), 139
Colliery, Dismantling an old, 23
Colombo University College, D. R. R. Burt appointed professor of zoology in, 292

Colonial: Office appointments, 101; 259; 420; 622; 776; 931; Development: and Scientific Research, 342; and Research, 364; Advancement, Co-operation in, 563; Policy and Scientific Research, 853; Development and Allied Co-operation, 888
Colour Printing, Modern 344
Coloured Families in the Port of Liverpool, Economic Status of, Kathleen Johnstone, 268
Columbia University, award of the Barnard gold medal to Prof. F. Joliot and Madame Irene Curie-Joliot, 666
Concealing Coloration tested by a Sparrow Hawk, Ll. C. Ingles, 902
Conflict, The, 795
Conjugated Ring Systems, Fluorescence and Oxidation in, Dr. J. Weiss, 744
Conservation: The Science and Practice of, Grass and Forage Crops, Dr. S. J. Watson. 2 Vols. (*Review*), 245
Constellations, An Easy Guide to the, J. Gall Inglis (*Review*), 656
Cook: Capt. James, R.N., F.R.S., The Life and Achievements of, Explorer, Navigator, Surveyor and Physician, Surgeon Rear-Admiral J. R. Muir (*Review*), 481
Cooper Union for the advancement of Science and Art, Eightieth annual report of the, 420
Copepods, Sand-dwelling, A. G. Nicholls, 595
Copper: Prehistoric, and some Experiments in Smelting, H. H. Coghlan, 310; Rossi Transition Curve for, The Second Maximum in the, P. J. G. de Vos, 387; Conductivity of, [1870], 474
Coprophagy in the Rabbit, Dr. A. Eden, 36
Cork, Interxylary, R. A. Diettert, 34
Corpus Callosum, Origin of the, 271
Cosmic: Ray Showers, Large, and Mesons, A. H. Wilson and F. Booth, 103; Rays: and Mesotrons, Dr. H. J. J. Braddick (*Review*), 141; Prof. R. A. Millikan (*Review*), 298; Recent Developments, Prof. P. M. S. Blackett (Guthrie lecture of the Physical Society), 343; Ray Showers: Penetrating, Dr. L. Jánossy and P. Ingleby, 511; Extensive, Barometric Coefficient of, M. G. E. Cosyns, 668; Intensities and Cyclones, Dr. Y. Nishina, Y. Sekido, H. Simamura and H. Arakawa, 703; Rays, Hard, Absorption of, and Mesotron Decay, B. Rossi, N. Hilberry and J. B. Hoag; E. Fermi, 903
Cosmology: a Text for Colleges, Prof. J. A. McWilliams. Second edition (*Review*), 816
Cosmos, Incompatibility in, T. M. Little, J. H. Kantor and B. A. Robinson, 979
Cotton: The Genetics of, Dr. S. C. Harland; Prof. R. R. Gates (*Review*), 124; The American Outlook on (*Review*), 280; History, Species, Varieties, Morphology, Breeding, Culture, Diseases, Marketing and Uses, Dr. H. Bates Brown. Second edition (*Review*), 280
Cozymase in Adrenalectomized Rats, Prof. J. Runnström, E. Sperber and E. Bárány, 106
Cracow University, German Activities at, 20
Cranberry, Cultivated, Production of Synthetic Mycorrhiza in the, Dr. M. C. Rayner and Ida Levisohn, 461
Creative Activity, The Nature of, V. Löwenfeld, translated by O. A. Oeser (*Review*), 662
Crime and Intelligence, Relationship of, Dr. I. Cohen (*Review*), 876
Croydon Natural History and Scientific Society, 621
Cryolite as an Insecticide, S. Marcovitch, 865
Crystalline Enzymes: the Chemistry of Pepsin, Trypsin and Bacteriophage, J. H. Northrup; Dr. Dorothy Crowfoot (*Review*), 990
Crystals, Organic, Molecular Rotation in, A. W. White, W. S. Bishop, B. S. Biggs and S. O. Morgan, 596
Cultural Relations of France and Britain, 757
Culture, Diet and Teeth, Dr. Helen Mellanby, 966
Cyclol Hypothesis, The, Dr. Dorothy Wrinch, 669
Cyclotron, The, Dr. W. B. Mann (*Review*), 1007
Cytochrome c, Properties of, Prof. D. Keilin and Dr. E. F. Hartree, 934
Cytologie, Experimentelle, Dr. H. H. Pfeiffer (*Review*), 477
Dalai Lama, Tibetan Ceremonial and the, 256
Date-Palm (*Phœnix dactylifera* Linn.), Mycorrhizal Habit in the, Y. Sabet, 782
Dead Sea, Algæ in the bed of the, Dr. B. Elazari-Volcani, 975
Deafness, The Handicap of, Irene R. and Dr. A. W. G. Ewing (*Review*), 813
Decalcification Fluid, A, R. A. C. Wilks, 671
Decarboxylation, Enzymic, Mechanism of, Dr. H. Weil-Malherbe, 106
Deccan, Inter-Trappean Flora of the, Prof. B. Sahni, 469
Deep-Sea Sediments, a Vacuum Core-Sampler for, Dr. H. Pettersson and B. Kullenberg, 306
Degeneracy and Dissociation Constants, Dr. H. O. Jenkins, 149
γ-Dehydrocholesterol, Irradiation of, J. W. M. Bunker, R. S. Harris and L. M. Mosher, 865
Delinquent as a Type, The, Dr. B. Karpman, 785
Democracy: For; edited by the "People and Freedom" Group (*Review*), 439; The Relation of Science to, R. Brightman (*Review*), 439; To-day and To-morrow, Dr. E. Beneš (*Review*), 439
Democratic Unity, International, 947
Demography of England and Wales, 459
Deoxycholic Acid, Production of Tumours in Mice by, Prof. J. W. Cook, Prof. E. L. Kennaway and N. M. Kennaway, 627
Design in National Life, R. Brightman (*Review*), 82
Development: Commissioners, Twenty-ninth Report of the, 547; Principles of, a Text in Experimental Embryology, P. Weiss; Dr. C. H. Waddington (*Review*), 952
Diacetyl, Fluorescence of, Almy, Fuller and Kinzer, 468
Diamond: in Europe, First, [1870], 198; Deposits of Tanganyika Territory, G. J. Williams, 393
Diaphoraѕes, Two Distinct, E. P. Abraham and E. Adler, 517
Diet in Health and Disease, edited by Sir Humphry Rolleston and Dr. A. A. Moncrieff (*Review*), 813
Diethylstilbœstrol: (4.4′ dihydroxy-α,β-diethylstilbene), A Colour Reaction of, E. Dingemanse, 825
Differential: Periodicity, Theory of, G. F. Sleggs, 153; Analyser, The, Prof. D. R. Hartree, 807
Diffusing Agents, Mucolytic Effect of Several, and of a Diazotized Compound, Prof. G. Favilli, 866
Dioscorea, genus, in the Belgian Congo, Notes on the, I. H. Burkill (*Review*), 494
Dioxadiene, R. K. Summerbell and R. R. Umhoefer, 35
Dioximaleic Acid Oxidase Action of Peroxidases, Dr. B. Swedin and Prof. H. Theorell, 71
Diphenyldiacetylene, Magnetic Anisotropy of, Dr. Kathleen Lonsdale, 148
Diphtheria, Prevention of, by Immunization, 345
Disease: and Race, S. Azmy Pasha and A. F. Zanaty, 98; -Resistant Plants, Breeding, Dr. F. W. Sansome, 690
Disintegration Produced by Deuterons, A New Type of, Dr. R. S. Krishnan and T. E. Banks, 777
Dissociation Constants, Degeneracy and, Dr. H. O. Jenkins, 149
Dropsy, Epidemic, in India, 594
Drosophila: Chromosomes of, Heterochromatin in the, B. P. Kaufmann, 33; Diurnal Rhythms in the Axolotl Larva and in, Dr. H. Kalmus, 72; *subobscura*, Effect of X-rays on, A. L. M. Christie, 113; Chronological Sex-Ratios in, Dr. G. Eloff, 463
Drug: Standardization (Harrison memorial lecture), A. D. Powell, 96; Activity, Mechanism of, 273; Addiction, Dr. W. B. Kennedy, 456; Standards for India, 716
Drugs Act ?, How do, Sir Walter Langdon-Brown, 273
Duggan-Cronin Bantu Gallery, Kimberley, 598
Dyes, Optically Sensitizing, Steric influence in, Dr. S. E. Sheppard, R. H. Lambert and R. D. Walker, 396

e, *m* and *h*, Evaluation of, Du Mond, 517
Early Man in Upper Egypt (*Review*), 84
Earth: Tremors: in Belgium, 100; in Scotland, 219; in New Jersey, Prof. W. A. Lynch, 258; Rotundity of the, [1870], 561; Regional Geology of the, Prof. H. H. Read (*Review*), 953

Earthing, Practical aspects of, E. Fawssett, H. W. Grimmett, G. F. Shotter and H. G. Taylor, 357

Earth's : Crust, Heat Flow in the, A. E. Benfield, 230 ; Interior, The, K. E. Bullen, 599

Earthquake : in Turkey, The, E. Tillotson, 13 ; in Central America, 24 ; The Ogasima (Japan), of May 1, 34 ; in Turkey, The, 62 ; 96 ; recorded on Magnetograph, 220 ; in Turkey, After-shocks of the, 259 ; Quetta, of 1935, K. R. Ramanathan and S. M. Mukherji, 393 ; Great Turkish, Aftershocks of the, 586 ; Recordings, Recent, 622 ; Insurance, Recent Trends in, A. C. Chick, 633 ; of Missouri, R. R. Heinrich, 979 ; during May, 1015

Earthquakes : Recent, 62 ; 143 ; in Greece, 219 ; Recent, 220 ; January, registered at Kew, 301 ; in Turkey, 346 ; during February, 1940, 460 ; near Great Dams, 508 ; Recent, 666 ; 701 ; in the United States and Italy, 817 ; Recent, 817 ; in Peru, 854 ; Recent, 892

East African People, An (*Review*), 877

Echo-Sounding, A New Application of, Dr. C. H. Mortimer and Dr. E. B. Worthington, 212

Economic : Warfare and National Effort, 361 ; Effort of War, The, R. W. B. Clarke (*Review*), 724 ; Warfare, Dr. P. Einzig ; R. Brightman (*Review*), 724

Economics : Mathematical Methods in, Prof. H. T. H. Piaggio (*Review*), 8 ; of War-time Export Trade, 472

Economy of a Primitive People (*Review*), 328

Edinburgh : University : Instruction for Women Students of Anatomy in, [1870], 160 ; award of the Cameron prize to Prof. E. C. Dodds, 385 ; Royal Botanic Garden, J. M. Cowan, 1014

Education : Principles and Practice of, Prof. W. G. de Burgh (*Review*), 241 ; in the Armed Forces, 526 ; in World Citizenship, 676 ; Economy in, A. G. Lowndes, 863

Educational Policy, Science and, 119

Egg : as Food, The, 788 ; Biological Nature of the, Dr. J. Needham, 788 ; Chemical Composition of the, Dr. Ethel M. Cruickshank, 788

Eggs : in the Diet, Nutritive Importance of, Dr. S. K. Kon, 788 ; Preservation of, Dr. R. B. Haines, 788 ; Cooking of, Miss Mary Andross, 789

Egypt : Geography of, J. Ball, 75 ; Southern Upper, Rock-drawings of, I : Sir Robert Mond Desert Expedition, Season 1936–1937 ; Preliminary Report, Dr. H. A. Winkler (*Review*), 84 ; Discovery of a Royal Tomb in, Prof. E. Montet, 300 ; Medical Research in, 739

Egyptian Royalty, Ancient, Relics of, 382

Einstein Equation, Viscosity of Suspensions and the, Dr. E. W. J. Mardles, 970

Elastic and Viscous Materials, Subjective Judgments of 'Firmness' in, Dr. G. W. Scott Blair and F. M. V. Coppen, 425

Electric : Motor, Industrial Use of an, [1870], 360 ; Discharge Lamps, Colorimetry of, 547 ; Cables and Fire Risks, S. W. Melsom, 752 ; and Magnetic Theory, Classical, Fundamentals of, Dr. G. Burniston Brown, 789 ; Potential Gradient of the Lower Atmosphere, C. W. Allen, 903 ; Surge Recording, Developments in, J. L. Candler, 982

Electrical Engineers, Institution of, award of the Faraday medal to Dr. Alexander Russell, 180 ; Thawing, C. W. Salt, 218 ; Timekeeping, F. Hope-Jones (*Review*), 326 ; Installation, Fire Fighting Equipment for, H. W. Swann and others, 358 ; Meter, A Sliding Rate, Dr. Unz, 396 ; Engineering Experiments : Theory and Practice, Prof. H. R. Reed and Prof. G. F. Corcoran (*Review*), 658 ; Development in Ireland, S. McEntee, 699 ; Invention and Re-Invention, W. T. O'Dea, 771 ; Engineers, The Institution of : Dr. A. P. M. Fleming (*Review*), 914 ; The History of the (1871–1931), R. Appleyard (*Review*), 914 ; Association, Incorporated Municipal, Activities of the, 929 ; Circuit-Breakers, Mechanical Integrity in the design of, M. C. Hunter, 1026

Electricity : Supply in Australia and New Zealand, 77 ; and Gas Inspection Services in Ottawa, 159 ; and Magnetism : an Introduction to the Mathematical Theory, Prof. J. B. Whitehead (*Review*), 298 ; Meters and Meter Testing, G. W. Stubbings (*Review*), 496 ; in Iron and Steel Works, Applications of, H. G. Weaver, 868 ; as applied to Metallurgy, Dr. A. P. M. Fleming (Menelaus memorial lecture), 929 ; and Magnetism for Students, S. R. Humby (*Review*), 1008

Electrochemistry : and Electrochemical Analysis : a Theoretical and Practical Treatise for Students and Analysts, Dr. H. J. S. Sand. Vol. 1 : Electrochemical Theory (*Review*), 137 ; Theoretical and Applied, Prof. M. de Kay Thompson. Third edition (*Review*), 811

Electrolytes, Colloidal, Prof. J. W. McBain, 702

Electron : Beams, Convergent, Diffraction of, Caroline H. MacGillavry, 189 ; Diffraction, Theory and Practice of, Prof. G. P. Thomson and Dr. W. Cochrane ; Dr. C. J. Davisson (*Review*), 367 ; Microscope at Toronto, The, Prof. E. F. Burton, J. Hillier and A. Prebus, 942

Electronic : Music, Dr. L. E. C. Hughes, 170 ; Charge, The, Prof. T. H. Laby and V. D. Hopper, 932

Electrons : Mesotrons into, Evidence for transformation of, Prof. E. J. Williams and G. E. Roberts, 102 ; 151

Elephantulus, Mechanism of, Ovulation and Corpus luteum formation in, Prof. C. J. van der Horst and J. Gillman, 974

Elliptic and Hyper-elliptic Integrals and Allied Theory, late W. R. Westropp Roberts (*Review*), 138

Elwes' Monograph of the genus lilium, A Supplement to, A. Grove and A. D. Cotton. Seven parts (*Review*), 913

Embryo Tissue, Vernalization of Fragments of, Dr. O. N. Purvis, 462

l'Embryologie expérimentale, Les progrès récents de, Prof. M. Caullery (*Review*), 952

Embryology : Recent American Investigations in, Prof. R. W. Sperry ; Prof. W. C. Allee and A. J. Finkel ; Miss Ethel Browne Harvey ; Prof. R. and E. L. Chambers ; Prof. H. L. Eastlick, 560 ; Human : Dr. F. H. A. Marshall (*Review*), 569 ; The Essentials of, Prof. G. S. Dodds. Second edition (*Review*), 569

Enamel Paints, Fluorescent, 585

Engineering : Applications of Photography to, A. H. Styring, 39 ; Practice, Statistics and, Dr. B. P. Dudding and W. J. Jennett, 117 ; Social Studies in (*Review*), 281 ; Physics and, New Units in, Suggestions for, 597 ; Type Tests in, 597 ; Design, Instructions in, Vol. 2 : Lattice Girder Bridge, H. P. Philpot (*Review*), 658

Engineer's : Manual, Prof. R. G. Hudson. Second edition (*Review*), 1006 ; Year-book of Formulæ, Rules, Tables, Data and Memoranda for 1940, 46th annual issue, revised under the direction of L. St. L. Pendred (*Review*), 1006

England to India Cable completed, [1870], 1030

Entomology : Medical, with special reference to the Health and Well-being of Man and Animals, Prof. W. B. Herms. Third edition (*Review*), 296 ; Economic (*Review*), 405

Enzymes : Dr. E. F. Armstrong (*Review*), 204 ; from Many Aspects (*Review*), 532

Enzymforschung, Ergebnisse der, Herausgegeben von F. F. Nord und R. Weidenhagen. Band 8 (*Review*), 532

Epeirogenic Earth Movements in East Greenland and the Depths of the Earth, L. R. Wager, 938

Epidemiology in Country Practice, Dr. W. N. Pickles (*Review*), 813

Erde, Regionale Geologie der, Herausgegeben von K. Andrée, H. A. Brouwer und W. H. Bucher. Band 2 : Palæozoische Tafeln und Gebirge. Abschnitt 2 : Northwestern Europe Caledonides. Prof. E. B. Bailey and Prof. O. Holtedahl. Abschnitt 3 : Mittel- und West-europa. Prof. H. Becker (*Review*), 953 ; Das Relief der, Versuch einer regionalen Morphologie der Erdoberfläche, Prof. F. Machatschek. Band 1 (*Review*), 1007

Escape with Me !, an Oriental Sketch-Book, O. Sitwell (*Review*), 809

Eskimo of Labrador, 678

Eskimos and Indians of Labrador, Anthropometric Observations on the, T. Dale Stewart, 678
Essex Oyster Beds, Effect of the Severe Frost of the Winter of 1939–40 on the Fauna of the, Prof. J. H. Orton, 708
Ethiopia: an Empire in the Making, F. Quaranta (*Review*), 168; Development in (*Review*), 168
Eton College, gift of a telescope to, [1870], 41

Fisher's, Mr., Various Essays, F. S. Marvin (*Review*), 683
Fishes, Air-breathing, Prof. B. K. Das, 519
Fizeau's Experiments on "Newton's Rings", [1870], 908
Flame Gases, Latent Energy and Dissociation in, Prof. W. T. David and B. Pugh, 896
Flies: Adult (Muscidæ), Relation between Corpus allatum and Ovaries in, Dr. Ellen Thomsen, 28
Flora of Madagascar, Dr. J. Hutchinson, 448
Fluorine, Geochemistry of, E. S. Shepherd, 596
Fodder Conservation, Science and Practice of, E. J. Roberts (*Review*), 245
Food: from Gardens and Allotments, Sir John Russell, 11; Rationing: Special Diets, Appointment of an advisory committee on, 101; Production and Food Control, Sir John Boyd Orr, 374; Investigation Board, Report of the, for the year 1938, 451; Research, Dr. T. F. Dixon, 451; Policy, War-time, 475; in War-time, edited by W. H. White, 665; Manufacture Preservation and Distribution of, Dr. L. H. Lampitt, 807; and the Housewife, Prof. V. H. Mottram, 853; Production without Artificial Fertilizers, Ysabel Daldy, 905; Policy, National, Co-ordination in, 910; Values at a Glance and How to Plan a Healthy Diet, Mrs. Violet G. Plimmer. Second edition (*Review*), 1005
Foods, The Chemical Composition of, R. A. McCance and E. M. Widdowson, 664
Foraminifera in Marine Deposits, Stratification of, H. G. Stubbings, 864
Forest: Trees, Provenance of, Intergrading among Plants in relation to the, Dr. R. Melville, 130: Entomology, Principles of, Prof. S. A. Graham. Second edition (*Review*), 496; Mensuration, Elementary, M. R. K. Jerram; with a Chapter on the Measurement of Forests by R. Bourne (*Review*), 496; Management and Erosion, Prof. E. P. Stebbing, 713: Products Research Board, Report for 1938, 829: Life of New Zealand, A Century in the, Dr. E. V. Laing, 943
Forestry, Role of Chemistry in, Dr. S. Krishna, '70
Fossil: Man of Monte Circeo, Italy, A. C. Blanc, 631; Link between North America and Asia, R. W. Brown, 751; Insect, The Oldest Known, D. J. Scourfield, 799
Fossils from the Belgian Ordovician, E. Maillieux, 229
France: The Birthrate in, 146; and England, Communication between, [1870], 236
Franklin Institute, Biochemical Research Foundation of the, Reports of the, Vol. 5, 1938–1939 (*Review*), 811
Franqui prize, Award of the, to Prof. P. Nolf, 968
Frazer: James George, the portrait of a Scholar, R. A. Downie (*Review*), 1004
Frazer's, Sir James, Notebooks (*Review*), 242
Freedom," "This, 833
French Grid, Transmission Lines on the, D. J. Tynan-Byrd, 772
Fruit: and Vegetable Products, Commercial, Prof. W. V. Cruess (*Review*), 530; Production: and Preservation, Prof. R. H. Stoughton (*Review*), 530; The Fundamentals of, Prof. V. R. Gardner, F. C. Bradford and H. D. Hooker, Jr. (*Review*), 530; Flies of Northern China, Y. Zia and Sicien H. Chen, 595
Fucales, Relationships of the, Dr. M. Delf, 637
Fuel in Science and Practice, Completion of its eighteenth volume, 344
Fuels, Imported, Survey of Substitutes for, 505
Fungi: Coprophilous, Life-histories of, W. M. Page, 113: Yorkshire, A Catalogue of, late F. A. Mason. Completed from the records of the late A. Clarke by Dr. J. Grainger (*Review*), 810
Fungus Disease, Biological Control of a, R. Leach, 153

γ-Radiation from ^{80}Br, Chemical action of, Dr. F. Fairbrother, 307
γ-Radiation, X- and, Volume Integration of dosage for, Dr. F. Happey, 668
Galactic: Rotation, Sun's Speed of, G. L. Camm, 230: Dynamics, Development of, and some Allied Problems, Prof. A. C. Banerji, 469
Gamma-Radiation, X- and, Wave-length Effect in the Reaction of Human Skin to, Dr. J. S. Mitchell, 105
Ganoderma lucidus (Leyss.) Karst. Effect of inversion of a small piece from the Fruit-body of, Growing *in situ* on the Trunk of *Casuarina equisetifolia*; Prof. S. R. Bose, 899
Garden, Science Lends a Hand in the, Sir Frederick Keeble (*Review*), 403

Gardening, Talks About (*Review*), 403

Gas-Turbine Set, Tests of a 4,000 kw., Prof. A. Stodola, 99

Gastropods, East Indian, Drs. Adam and Leloup, 229

Gattermann Synthesis of Aldehydes, A. G. Mistretta and Prof. F. F. Nord, 387

Gaz, Décharge électrique dans les, Prof. M. Laporte (*Review*), 500

Gelatin, Mutarotation of, M. P. Balfe, 429

Geological: Time, Measurement of, [1870], 274; 360; Calculus, The, [1870], 436; Sciences, The Birth and Development of the, Dr. F. D. Adams (*Review*), 478; Records, Preservation of, Dr. M. Macgregor, 576; Survey of Great Britain, Summary of Progress of the, 1936 and 1937, 790

Geology: of India, D. N. Wadia. Second edition; Dr. G. de P. Cotter (*Review*), 88; for Engineers, Brig.-Genl. R. F. Sorsbie. New edition (*Review*), 138; Historical, Outlines of, Prof. C. Schuchert and Prof. C. O. Dunbar. Third edition (*Review*), 138; Elements of, with reference to North America, Prof. W. J. Miller. Second edition (*Review*), 295; A Source Book in, Prof. K. F. Mather and Dr. S. L. Mason (*Review*), 478; The History of, V. A. Eyles (*Review*), 478; of London and South-East England, G. M. Davies (*Review*), 497; Submarine, Geophysical Study of, Dr. E. C. Bullard, 764; in Great Britain: Reports for 1936 and 1937, 790

Gephyrea, Japanese, H. Satô, 710

Gerland's Beiträge zur Geophysik, Supplement Band 4. Ergebnisse der Kosmischen Physik, Band 4: Physik der Hydro- und Lithosphäre, Herausgegeben von V. Conrad (*Review*), 760

German: Otorhinolaryngological Society, award of the Alfred Denker foundation prize of the, to Dr. L. v. Hofmann, 302; Universities, foreign students in, 740

Germany: Science Education in, [1870], 398; Marriages in, Jan. to June 1939, 460

Gesture, The Language of, Dr. M. Critchley (*Review*), 814

Glass: Bending of, under Long Continued Stress, Lord Rayleigh, 29; Industry, Physics in the, Prof. W. E. S. Turner, 446; Technology, Society of, Dr. S. B. Bagley elected president of the, 666; Ultra-Violet Transparency of, Change of, with Temperature, Dr. W. J. Arrol, 861

Glutamic Acid of Proteins, Prof. A. C. Chibnall, M. W. Rees, E. F. Williams and Dr. E. Boyland, 311; Dr. A. Konikova; Dr. B. W. Town, 312

Glycolysis in Embryos, Meyerhof and Perdigon, 631

Goethe medal for art and science, award of the: to Prof. Max Borst, 146; to Prof. H. E. Hering, 931

Gold Coast: New Shrines on the, Miss M. J. Field, 864; Alluvial Gold Dredging in the, 891

Golgi: Apparatus, The, Prof. J. B. Gatenby (*Review*), 481; -Körper, Form- und Stoffwechsel der, Dr. G. C. Hirsch (*Review*), 481

Gondwanaland, The Indian Fragment of, Dr. L. Dudley Stamp (*Review*), 725

Gospel, The, and the Church: a Study of Distortion and its Remedy, Rev. Canon Charles E. Raven (*Review*), 329

Gossypium Raimondii Ulbr., Relationship of, Prof. T. Boza-Barducci and R. M. Madoo, 553

Grain Heaps, Temperature of, R. Attia, 711

Graphite: Fermi-Dirac Energy Distribution of the Metallic Electrons in, Landau Diamagnetism and the, Prof. K. S. Krishnan, 31; Electronic Specific Heat of, Prof. K. S. Krishnan, 388

Graptolithina, Dr. O. M. B. Bulman (*Review*), 1004

Grassland, Additional, Ploughed-up, in England and Wales, 854

Great Britain, Location of Industry in, 601

Greek Poetry: Nature in, Studies partly Comparative, late Dr. G. Soutar (*Review*), 641

Greenland: Insects of, A Revised Index of the, K. J. Henriksen, 112; North-West, Glaciology of, J. W. Wright, 154; East: Petrology of, Dr. L. Hawkes, 197; Petrology of the Skaergaard Intrusion, Kangerdlugssuag, L. R. Wager and Dr. W. A. Deer, 197; Epeirogenic Earth Movements in, and the Depths of the Earth, L. R. Wager, 938

Greenwich: Royal Observatory, Annual Report of the Astronomer Royal, 980

Grey Owl: Naturalist (*Review*), 165

Growth Factors, Effect of the Suspending Medium on the Production of, by Injured Cells, Prof. J. R. Loofbourow and Sister Cecilia Marie Dwyer, 185

Gull, Black-headed, Survey, P. D. Hollom, 217

Gypsies, Nomad, of Hungary, Istvan Nagy, 192

Gypsy Luck in Serbia, A. Petrovič, 229

Hæmoglobin in Lumbricus, Function of, and of Chlorocruorin in Sabella, Prof. H. Munro Fox, 781

Hæmolytic Streptococci, Serological Properties of Extracts of, prepared by Ultrasonic Vibrations, Dr. H. Loewenthal and Prof. F. L. Hopwood, 858

Hæmopoietic System of Human Beings, Effect of Synthetic Vitamin B_6 on the, R. W. Vilter, H. S. Schiro and Prof. T. D. Spies, 388

Hair, Bobbed, Inheritance of, S. E. Stoddard, 516

Haiti: Jamaica and, Myths and Magic in (*Review*), 49; Prehistory in, F. G. Rainey and I. Rouse, 785

Half-Breed: the Story of Grey Owl (Wa-Sha-Quon-Asin), Lovat Dickson (*Review*), 165

Handwriting: Analysis of, an Introduction into Scientific Graphology, H. J. Jacoby (*Review*), 645; The Study of, Sir Richard Paget, Bt. (*Review*), 645

Hardwood Timbers, Moisture Relations of, Influence of Cell Wall Composition on the, S. H. Clarke and C. B. Pettifor, 424

Haulage Precautions in Mines, 315

Hebrew University of Jerusalem, Annual Report, 1938–39, 383

Health: Education, Handbook of Suggestions of, 346; Investigations, International, 518

Hearing: Tests, H. C. Montgomery, 79; and Equilibrium, H. Macnaughton-Jones (*Review*), 662

Heart, Human, Force of the, [1870], 41

Heat: a Text-book of, Prof. H. S. Allen and R. S. Maxwell. 2 parts (*Review*), 86; Foundations and Development of, Dr. R. A. Houstoun (*Review*), 86; Units, [1870], 599

Hebrew University, Jerusalem, Extension of the, 622

Helium Production in the United States, Dr. C. W. Siebel, 257

Helmholtz, Prof., elected to the Paris Academy of Sciences, [1870], 80

Herbals, Sixteenth-Century Colouring of, Dr. Agnes Arber, 803

Hereditary Genius, [1870], 436

Heriot-Watt Technical College, impending retirement of Prof. T. Slater Price, 926

Herring, Young, Growth and Feeding of, S. M. Marshall, A. G. Nicholls and A. P. Orr, 467

Higher School Certificate Examination, 620

Hippocrates, The Genuine Works of, translated by Dr. F. Adams (*Review*), 297

Histamine, Kallikrein and, Dr. M. Rocha e Silva, 591

Hochfrequenztechnik, Lehrbuch der, Dr. F. Vilbig. Zweite Auflage; (*Review*), 137; Hochfrequenztechnik, Lehrbuch der, Schrifttumsverzeichnis zum, Dr. F. Vilbig. Zweite Auflage (*Review*), 137

Holmium, Atomic Weight of, O. Hönigschmid, 633

Honey Bees, Acarine Disease of, Origin of the Frow Remedy for, Miss A. D. Betts and D. Morland, 824

Hormones: and the Garden, M. A. H. Tincker and C. H. Unwin, 112; in Plants, Transverse Distribution of, E. D. Brain, 316; Animal, T. H. Hawkins (*Review*), 763; in Invertebrates, Prof. B. Hanström (*Review*), 763

Horrox, Astronomical Investigations of, Prof. F. J. M. Stratton, 584

Horticultural Plants, Propagation of, G. W. Adriance and Prof. F. R. Brison (*Review*), 762

Hospital Reform, Need of, [1870], 274

Human: Skin, Wave-length Effect in the Reaction of, to X- and Gamma-Radiation, Dr. J. S. Mitchell, 105; Heredity, Bureau of, Activities of the, 183; Genera and Species, Dr. S. Zuckerman, 510

Humpback Whales off West Australia, Prof. W. J. Dakin, 783; G. Rayner, 784

Huxley's Teaching at Edinburgh, Prof. J. Ritchie, 965

Huygens' Principle: Prof. H. T. H. Piaggio (*Review*), 531; The Mathematical Theory of, Prof. B. B. Baker and Prof. E. T. Copson (*Review*), 531

Hydraulics, Applied, A Text Book of, Prof. H. Addison. Second edition (*Review*), 141

Hydrocarbons: Dr. E. F. Armstrong (*Review*), 442; Physical Constants of, Vol. 1: Paraffins, Olefins, Acetylenes and other Aliphatic Hydrocarbons, Dr. G. Egloff (*Review*), 442; Energies of, Calculations on the, G. J. Kynch, E. H. Lloyd and Dr. W. G. Penney, 777

Hydrogen: Lyman Radiation, Absorption of, by Atmospheric Gases, S. E. Williams, 68; Line 1215·7 A., Absorption of the, by Air, W. M. Preston, 623; Photochemical Oxidation of, H. A. Smith and A. Napravnik, 827; Bond, The, Dr. C. E. H. Bawn, 846; Bentonites, Dilute Solutions of, Formation of Aggregates and Structures in, Prof. J. N. Mukherjee and Dr. N. C. Sen Gupta, 971; Spectrum, Precision Measurements in the, J. W. Drinkwater, Sir Owen Richardson and W. E. Williams, 1026

Hyperprothrombinæmia during Pregnancy, Dr. O. Thordarson, 305

Ice Formation: Unusual, in Wiltshire, E. R. Gunther, 428; in Worcestershire, A. A. Newbold, 514

Illinois University, Dr. J. W. Lloyd appointed acting head of the Department of Horticulture in the College of Agriculture of, 740

Imperial: Economy, Establishment of an, E. du Vivier de Streel, 301; Cancer Research Fund, Thirty-seventh annual report of the, 775

Imperialism and Service, 852

India: Hydro-Electric Development in, 23; Geology of, D. N. Wadia. Second edition; Dr. G. de P. Cotter (*Review*), 88; Agricultural Meteorology in, Research in, 113; Zoology in, Future of, 163; British, The Fauna of, including Ceylon and Burma, edited by Lt.-Col. R. B. S. Sewell. Mammalia, Vol. 1: Primates and Carnivora (in part), Families, Felidae and Viverridae, R. I. Pocock (*Review*), 164; The Mammals of, D. Seth-Smith (*Review*), 164; Meteorology in, 182; Seismological data from, Dr. S. K. Banerji, 193; Southern, Ancient Wall-Painting in, S. Paramasivan, 195; Medical Council of, Prof. Bidhan Chunder Roy elected president of the, 259; Instructional Films in, C. F. Strickland, 458; Meteor Observations from, M. A. R. Khan, 468; Upper Cretaceous and Lower Eocene Beds of, with special reference to the Cretaceous-Eocene Boundary, Prof. L. Rama Rao, 470; Air Circulation over, 471; and its Neighbourhood, General Circulation of the Atmosphere over, K. R. Ramanathan and K. P. Ramakrishnan, 471; Hydro-Electric Development in, 509; Scope of Prehistoric and Anthropological work in, Rao Bahadur K. N. Dikshit, 520; Crop Production in, Prof. Jai Chand Luthra, 521; Hindu and Moslem in, 544; Epidemic Dropsy in, 594; Drug Standards for, 716; Southern, Rabies Treatment in, 739; Malaria in, Prevention of, Recent Advances, Sir Malcolm Watson, 878; Government of, Prof. S. S. Bhatnagar lent to the, as director of scientific and industrial research, 968

Indian: Origins, Some, in the light of Astronomical Evidence, S. N. Chakravarti, 38; Sculpture and Architecture, Dr. F. H. Gravely and C. Sivaramamurti, 457; Science Congress Association: Madras meeting, 469; 519; Archæological Studies, Sir Leonard Woolley and, 621; Peninsula and Ceylon, The, Dr. G. de P. Cotter (Regionale Geologie der Erde, Herausgegeben von K. Andrée, H. A. Brouwer und W. H. Bucher). Band 1 (Absch. 6) (*Review*), 725

Indian Science Abstracts, Part 1, 65

Indian Farming, No. 1, 585

Industrial: Population, Distribution of the, Royal Commission on the, Report, 634; Health in War-time, 664; Scientists, Economic Problems of, H. N. Linstead and others, 715; Workers, Training, B. Ungerson, 754

Industry: in Great Britain, Location of, 601; Location of, R. Brightman (*Review*), 916; The Location of, and the Depressed Areas, Prof. S. R. Dennison (*Review*), 916

Infectious Diseases: Acute, a Handbook for Practitioners and Students, Dr. J. D. Rolleston and Dr. G. W. Ronaldson. Third edition (*Review*), 1009

Infra-Red: Spectra and the Structure of Molecules, Dr. W. H. J. Childs and Dr. H. A. Jahn, 646; Drying, 775; OH Band and Association, J. Errera and others, 942

Initial Series from Tres Zapotes, Vera Cruz, Mexico, An, M. W. Stirling, 594

Insect: Pests of Crops in England and Wales, Dr. A. D. Imms, 359; Cuticle, Permeability of, H. Hurst, 462; Embryology, Recent Advances in, Mithan Lal Roonwal, 674

Insectes, Ce qu'il faut savoir des, G. Portevin. Vol. 2: Coléoptères et hémiptères (*Review*), 811

Insects: and Disease, Air Transport, F. G. Sarel Whitfield; Dr. A. D. Imms, 76; Destructive and Useful, Their Habits and Control, Prof. C. L. Metcalf and W. P. Flint. Second edition (*Review*), 405; Ecology and Control of, Dr. Hem Singh Pruthi, 520; The World of, Prof. C. D. Duncan and Prof. G. Pickwell (*Review*), 1005

Instinct, Inheritance of, C. E. Keeler and H. C. Trimble, 865

Insulin Hypoglycæmia and the Central Nervous System, El Gellhorn, 516; Molecule, Patterson Projection of the Skeletons of the Structure proposed for the, Dr. Dorothy Wrinch, 1018

Intelligence: Cortical Localization of, H. M. Hildreth, 829; and Crime: a Study of Penitentiary and Reformatory Offenders, S. H. Tulchin (*Review*), 876

International: Health Organizations, Development of, Dr. R. A. Lyon, 217; Affairs, Viscount Halifax, 381; Unity in War and Peace, 525; Air Force, Suggestions for an, 697; Seismological Summary, Jan., Feb., and March 1934, 701; Spirit in Science, 736; Relief Union, The, C. Gorgé, 808; Fisheries Research in the Atlantic, 943; Democratic Unity, 947

International Journal of Agrarian Affairs, No. 1, 145

Intestinal Sugar Absorption and Phosphate Metabolism, Dr. L. Laszt, 899

Invar, Thermal Expansion of, Prof. L. F. Bates and J. C. Weston, 550

Ionization Gauge, A New, R. S. Morse and R. M. Bowie, 712

Iraq, Meteorology in, 145

Ireland, Southern, River Development in, A. Miller, 75

Iron: Protecting, from Atmospheric Influences, [1870], 318; and Steel Institute, J. Craig elected president; award of the Bessemer gold medal to Dr. A. McCance, an Andrew Carnegie silver medal to B. W. L. Ljunggren, the Williams prize to W. B. Lawrie and W. T. Wilson; E. Schneider nominated an honorary member of the, 548

Irrigation Through the Ages, Influence of the Mechanical Mind on the Development of, E. B. Ball, 717

Islam's Contributions to Science, Dr. E. J. Holmyard (*Review*), 5

Isochromats, Determination of h/e by the method of, Dr. Per Ohlin, 223

Isotopes, Separation of, R. Fleischmann, 712

Italian Empire, Fishery Research in the, 545

Jamaica and Haiti, Myths and Magic in (*Review*), 49

Japan Metallurgy Society, Sir Harold Carpenter awarded the Honda prize of the. 509, 736

Japanese Volcano, Explosive Activities of a, T. Minakami, 473

Java Sea, Preliminary Plankton Investigations in the, Dr. H. C. Delsman, 41
Jersey, Prehistory of (*Review*), 684
Jerusalem, Archæological Investigations in, C. N. Johns, 507

Kala-Azar, Antimony Treatment of: Dr. E. S. Horgan and Dr. R. Kirk. 228 ; Sir Upendranath Bramachari, 546
Kaleidoscope, The Generalised, S. Melmore, 778
Kallikrein and Histamine, Dr. M. Rocha e Silva, 591
Kant's Views on Space, [1870], 118
Kazakhstan, L'Asie centrale soviétique et le, C. Steber (*Review*), 295
Kipsigis, The Social Institutions of the, Dr. J. G. Peristiany (*Review*), 877
Kittiwake, Curious Nesting-place of, K. Schmidt-Nielsen, 864
Knowledge and Character, Dr. Maxwell Garnett (*Review*), 241
Kontinente, Die Entwicklung der, und ihrer Lebewelt, Prof. T. Arldt. Zweite Auflage. Band 1 (*Review*), 497
Kornerupine from Ceylon : a New Occurrence, B. W. Anderson and C. J. Payne, 266
Kristallographie, Geometrische, und Kristalloptik und deren Arbeitsmethoden : Eine Einführung, Dr. F. Raaz und Dr. H. Tertsch (*Review*), 812
Kurds of the Rowanduz Area, Iraq, E. R. Leach, 710

Lac, Uses of, Dr. H. K. Sen and S. Ranganathan (*Review*), 815
Laccase from the Latex of Lacquer Trees, Some Properties of, Prof. D. Keilin and Dr. T. Mann, 304
L'Acide ascorbique dans la cellule et les tissus, Prof. A. Giroud (*Review*), 294
Lake Toba, North Sumatra, Origin of, van Bemmelen, 230
Lamp, The Story of the (and the Candle), F. W. Robins (*Review*), 407
Land Drainage and Reclamation, Prof. Q. C. Ayres and Prof. D. Scoates. Second edition (*Review*), 815
Landau Diamagnetism and the Fermi-Dirac Energy distribution of the Metallic Electrons in Graphite, Prof. K. S. Krishnan, 31
Landscape Meteorology and its Reflection in Art and Literature, L. C. W. Bonacina, 22
Lantern Slides, Making of, G. H. Bell, 145
Lapps, Finnish, Teeth of, Dr. Helen Mellanby, 978
Larvæ of Decapod Crustacea, Bibliography of the, Dr. R. Gurney (*Review*), 494
Laue Photographs, Anomalous X-ray Reflections on, Dr. I. E. Knaggs, Dr. K. Lonsdale, Dr. A. Müller and A. R. Ubbelohde, 820
Lead : Tetra-acetate, Oxidation with, J. M. Grosheintz, 353 ; Etching Effect, A, Dr. J. A. Smythe, 704
Leaf Respiration, Effect of Rubbing on, L. J. Andus, 555
'Leaf Carpet,' Microbiology of the, D. J. Scourfield, 785
League of Nations : Non-Political work of the, 97 ; Report of the Health Committee of the, 518
Learned Societies, A Building for the, [1870], 755
Leeds University, Dept. of Coal-Gas and Fuel Industries, Report for 1938–39, 344
Leeuwenhoek, Antonie van, Journal of Microbiology and Serology, Vol. 6, No. 1, 459
Left-handedness, [1870], 599
Length, Unit of, [1870], 984
Level Measurement and Control, 314
Lewis's Medical and Scientific Lending Library, Catalogue of, new edition, part 2, 66
Liberty : The Challenge to, an address given at Oxford, Viscount Halifax (*Review*), 834 ; The Ranks of, 985
Life : Looking at, an introduction to Biology, A. M. S. Clark and G. Buckland Smith (*Review*), 136 ; and Living, Prof. F. Wood Jones (*Review*), 244 ; The Origin of, Prof. J. Stanley Gardiner (*Review*), 277 ; My, Havelock Ellis (*Review*), 759
Life's Beginning on the Earth, Prof. R. Beutner (*Review*), 277
Light, A Text Book on, Dr. A. W. Barton (*Review*), 141
Lighting : Appliances, History of (*Review*), 407 ; Daytime, of Blacked-out Factories, R. Maxted and J. Bertram, 928
Lilac, Graft Blight of, C. H. Cadman, 230
Lilium, The genus, Sir W. Wright Smith (*Review*), 913
Linen Industry Research Association, Dr. A. J. Turner appointed director of research of the, 806
Ling Physical Education Association, awards to members of the, 740
Linkage, Calculation of, W. L. Stevens, 193
Linnean Society : presentation of the Linnean medal to Sir Arthur Smith Woodward and of the Crisp award and medal to D. J. Scourfield, 806 ; election of officers, 854 ; during War-time, 1012
Liquid State, Theories of the, Prof. N. F. Mott, 801
Liquids, Cohesion of, R. S. Vincent, 970
Lister Institute, Prof. C. R. Harington appointed a representative of the governing body of the, 1015
Listeria : Change of Name for a genus of Bacteria, J. H. Harvey Pirie, 264
Literature : Phenomenology of, Prof. H. J. Rose (*Review*), 761 ; The Growth of, H. Munro Chadwick and N. Kershaw Chadwick. Vol. 3 (*Review*), 761
Live Stock Policy during War-time, Dr. C. Crowther, 284
Lloydia, a New Biological Journal, 24
L.M.S. Railway, award of the Herbert Jackson prize to H. I. Andrews, 302
Local Government, Scientific Planning of, 161
London : School of Hygiene and Tropical Medicine, Report for 1938–39, 218 ; University, conferment upon Dr. F. C. Chalklin of the title of reader in physics ; conferment of doctorates, 523 ; 1030 ; War-time Mortality in, Dr. P. Stocks, 826
Louse : The, and How to Deal with it, 345 ; The, and Louse-born Diseases, Dr. A. D. Imms (*Review*), 723 ; The, an Account of the Lice which Infest Man, their Medical Importance and Control, Prof. P. A. Buxton (*Review*), 723
Low Countries : War in the, 771 ; Fauna and Flora of the, 806
Lubricant Films, Effect of Temperature on, Dr. D. Tabor, 308
Lunar Tide in the Atmosphere, Prof. S. Chapman, 257
Lyell's Geological Texts, Prof. G. R. Wieland, 227

McComb-Romberg Seismometer, The, J. H. Nelson and H. E. McComb, 159
Machine Calculation, Modern, with the Facit Calculating Machine Model Lx, H. Sabielny. Translated and revised by Dr. L. J. Comrie and Dr. H. O. Hartley (*Review*), 497
Macromolecules, 248
Madagascar : Demography of, Dr. F. Randriamanana, 98 ; Flora of, Dr. J. Hutchinson, 448
Magnetic Mine, Countering the, 415
Magnetism and the Structure of Matter, Dr. Kathleen Lonsdale, 57
Magnetization : Energy Changes accompanying, Prof. L. F. Bates and J. C. Weston, 188 ; The Domain Theory of, Prof. L. F. Bates (*Review*), 606
Magnets, Remagnetizing, used in D. C. Meters, R. Callender, 903
Maize : Breeding, J. Philp, 556 ; Origin of, P. C. Mangelsdorf and R. G. Reeves, 711 ; Pollination in, W. R. Singleton, 979
Malaria : A Probable Cause of, [1870], 398 ; as an Occupational Disease, Dr. J. C. Lévy, 853 ; in India : Prevention of, Recent Advances, Sir Malcolm Watson, 878 ; Deaths of Natives in the Transvaal from, 892
Malaya, Higher Education in, 144
Mammals of India, The, D. Seth-Smith (*Review*), 164
Man : -Power, Scientific, Utilization of, 43 ; Rights of, Civilization and the, 237 ; The Future of, as an Inhabitant of the Earth, Dr. K. F. Mather, 663 ; The Discovery of, the Story of the Inquiry into Human Origins, S. Casson (*Review*), 809 ; The Phylogeny of, Prof. W. E. Le Gros Clark, 981

Manchester University: Dr. C. W. Wardlaw appointed Barker professor of Cryptogamic Botany, 523, 543 impending retirement of Prof. W. H. Lang, 543
Mangarevan Archæology, K. P. Emory, 392
Man's Line of Descent, Paratypical forms in, Prof. G. Montandon, 545
Maori Bowls, A. G. Stevenson, 229
Margarine, Prof. J. C. Drummond, 53, 60
Marine: Animals, Eggs of, Basic Methods for Experiments on, Dr. E. E. Just (*Review*), 494; Organisms, Distribution of, Lieut.-Col. R. B. Seymour Sewell, and others, 732; Biological Association, Journal of the, Vol. 24, No. 1, 1027; Biology, Recent Advances in, Dr. N. B. Eales, 1027
Marinobufagin, Arenobufagin and Acetyl-marinobufagin, Acetyl content of, Dr. V. Deulofeu, E. Duprat and R. Labriola, 671
Marlin, Black and the Striped, W. K. Gregory and G. M. Conrad, 555
Marquesan Insects, III, 392
Marriage-rate in War-time, 217
Maternal Deaths in Calcutta, 385
Mathematical: Tables: Vol. 7: The Probability Integral, late W. F. Sheppard (*Review*), 139; Recreations and Essays, late W. W. Rouse Ball. Eleventh edition, revised by Dr. H. S. M. Coxeter (*Review*), 444
Mathematician, Plea for the, [1870], 41
Mathematics: Useless, Prof. J. B. S. Haldane (*Review*), 444; for Actuarial Students, H. Freeman. 2 parts (*Review*), 659; Higher, with Applications to Science and Engineering, Prof. R. S. Burington and C. C. Torrance (*Review*), 659
Matter: the structure of, Magnetism and, Dr. Kathleen Lonsdale, 57; in Bulk, Properties of, Prof. N. F. Mott (*Review*), 239; Motion and Electricity: a Modern Approach to General Physics, H. De Wolf Smyth and Prof. C. W. Ufford (*Review*), 298; Structure of, Thermodynamics and the, A. R. Ubbelohde, 488
Meat Packing Industry, Illness in, H. P. Brinton, H. E. Seiffert and Elizabeth S. Frasier, 419
Mechanical Engineers, Institution of, A. Binns elected president of the, 346
Mechanics: Theoretical, a Vectorial Treatment, Prof. C. J. Coe (*Review*), 141
Mechanism, Principles of, F. Dyson. Third edition (*Review*), 142
Medicago Hybrids, Interspecific Hybridization in, G. F. Ledingham, 595
Medical Research Council, Report of the, for the year 1938–1939, 615
Melanesians and Europeans, Feet of, C. S. James, 153
Men and Ideas: Essays, Graham Wallas (*Review*), 915
Mercury, Gas-free, First Benedicks Effect in, as influenced by the Mean Temperature, Prof. C. Benedicks and P. Sederholm, 148, 666
Mesons: Scattering of, and the Magnetic Moments of Proton and Neutron, Dr. W. Heitler, 29; Large Cosmic Ray Showers and, A. H. Wilson and F. Booth, 103
Mesotron: obey Bose-Einstein or Fermi-Dirac Statistics? Does the, P. L. Kapur, 69; Showers, Photographic Plates as Detectors of, Prof. D. M. Bose and Miss Biva Chowdhry, 894
Mesotrons into Electrons, Evidence for Transformation of, Prof. E. J. Williams and G. E. Roberts, 102; 151; Prof. E. J. Williams and G. R. Evans, 818
Metal and its Ions in Solution, Exchange between a, B. V. Rollin, 711
Metallography: Principles of, Prof. R. S. Williams and Prof. V. O. Homerberg. Fourth edition (*Review*), 660; Microscopical, Practical, Dr. R. H. Greaves and H. Wrighton. Third edition (*Review*), 814
Metallurgy for Engineers, E. C. Rollason (*Review*), 814
Metals: Institute of, election of officers, 586; The Physical Examination of, B. Chalmers. Vol. 1: Optical Methods (*Review*), 660; Oxidation of, and the Formation of Protective Films, Prof. N. F. Mott, 996
Metamorphism: a Study of the Transformations of Rock-Masses, late Dr. A. Harker. Second edition (*Review*), 644
Meteor: Velocity, Determination of, from Zenith Attraction, Hideo Inouye, 35; A Notable, Prof. C. Störmer, 195
Meteorite, Age of a, W. C. Schumb, R. D. Evans and J. L. Hastings, 431
Meteorites: Microscopical Investigation of, [1870], 235; Whence Come, [1870], 869
Meteorological: Office, Report of the, for the year ending March 31, 1939, 64; Blockade, [1870], 118
Meteorology: for Aviators, Dr. R. C. Sutcliffe (*Review*), 140; in India, 182
Methylcholanthrene, Action of, on Normal Tissue Cultures, W. R. Earle and C. Voegtlin, 785
Metric Weights and Measures, [1870], 318
Metropolitan Water Board, Thirty-third Annual Report, Lt.-Col. E. F. W. Mackenzie, 830
Mice, Congenital Hyperglycæmia in, Dr. H. Grüneberg and Prof. J. B. S. Haldane, 704
Microbiology, Medical, Prof. K. L. Burdon (*Review*), 813
Microscope: Made Easy, The, A. L. Wells (*Review*), 293; Objectives, Depth of Focus of, D. G. Beadle, 1018
Microseisms and Transmission of Atmospheric Disturbances, K. Sezawa and K. Kanai, 154
Microtechnique, Elementary, H. A. Peacock. Second edition (*Review*), 1005
Milk: and Nutrition, 273; in Schools Scheme, Resumption of the, 420; The Chemistry of, Dr. W. L. Davies. Second edition (*Review*), 657
Millipedes, Systematics of, Rev. S. Graham Brade-Birks (*Review*), 87
Mine Rescue Telephone, R. C. Woods, 235
Mineral Resources: Prof. R. N. Rudmose Brown, 232; of the British Empire, 258
Mines, Haulage Precautions in, 315
Mistletoe, Magic and Medicine, Dr. L. Kanner, 99
Mohammedan Calendar and the First Visibility of the New Moon in Egypt, J. H. Reynolds, 751
Molecular Structure: and Raman Spectroscopy, Prof. C. K. Ingold (*Review*), 406; Viscosity and, Dr. H. Mark and R. Simha, 571
Molecules: Simple, Relationship between the Critical Temperatures, Boiling Points and the Parachor Values of, D. T. Lewis, 551; structure of, Infra-red Spectra and the, Dr. W. H. J. Childs and Dr. H. A. Jahn, 646
Monochromatic Image in the Spectrohelioscope, Use of, M. A. Ellison, 154
Montevideo, Foundation of an institute for Experimental Hygiene at, 968
Moscow in Figures, 100
Mosquitoes and Filariasis, S. M. K. Hu, 632
Mother of Pearl Clouds observed in Southern Norway during 1926–34, Height of, Prof. C. Störmer, 221
Mound Exploration in the Tennessee Valley, U.S.A., 128
Mount Carmel, The Stone Age of: Abbé H. Breuil (*Review*) 837; The Fossil Human Remains from the Levalloiso-Mousterian. Vol. 2, T. D. McCown and Sir Arthur Keith (*Review*), 837
Mouse (*Mus musculus*), Presence of the Sperm Middle-Piece in the Fertilized Egg of the, Dr. R. A. R. Gresson, 425
Mucinase and Tissue Permeability, D. McClean and C. W. Hale, 867
Murchison Range, Mineral Deposits of the, van Eeden, Kent, Brandt and Partridge, 193
Murray, John, Expedition, Fishes of the, J. R. Norman, 978
Museum: Exhibit, A New Kind of, B. Washburn, 508; Exhibitions, War-time, 929
Museums of Natural History, [1870], 984
Music, Electronic, Dr. L. E. C. Hughes, 170
Musical Pitch of Orchestras, G. B. Madella, 396
Mycological Taxonomy, J. A. Nannfeldt; Miss E. M. Wakefield, 113
Myriapoda 3, Polydesmoidea II, Fam. Leptodesmidæ, Platyrhachidæ, Oxydesmidæ, Gomphodesmidæ, Dr. Graf Attems (*Review*), 87
Myxophyceæ, Aspects of the, Prof. Y. Bhâradwâja, 519

Nahrung und Ernährung: Altbekanntes und Neuerforschtes vom Essen, Dr. H. Glatzel (*Review*), 816

Nasion in the Living, Measurement of the, K. P. Chattopadhyay, 674

Natal University College, Pietermaritzburg, Prof. F. L. Warren appointed professor of chemistry in, 420

National: Physical Laboratory, retirement of Dr. C. H. Desch; appointment of Dr. C. Sykes as superintendent of the department of Metallurgy and Metallurgical Chemistry, 101; Book Council, Report for 1938–39, 219; Union of Students: London Medical Committee, 583; Physical Laboratory, T. Smith appointed superintendent of the new department of Light, and R. S. J. Spilsbury superintendent of the Electricity department, 622; Institute of Agricultural Botany, annual report of the, 1938–39, 665; Collections in London or in the Country?, Dr. P. R. Lowe, 889; Radium Trust and Radium Commission, Tenth annual reports of the, 891; Food Policy, Co-ordination in, 910; Expenditure, Select Committee on, Fourth Report from the, 911; Physical Laboratory, Report for 1939, 967; Character, The Illusion of, Hamilton Fyfe (*Review*), 1001

Nation's Food, appointment of a scientific advisory committee on the, 887

Native Races: and Tuberculosis, 144; of America: The, a Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer, arranged and edited by R. A. Downie (*Review*), 242

Natural: History, Bibliography of, Society for the, election of officers, 259; Science at Cambridge, [1870], 360; Science Schools at Rugby, [1870], 398; History Collections, The, [1870], 908

NATURE, First number of the second volume of, [1870], 717

Nature: in the Classics, D. Caclamanos (*Review*), 641; Parade, F. W. Lane (*Review*), 657; Legislation and, [1870], 679

Naval Architects, Institution of, award of the premium of the, to A. Nicholls and of the Wakeham prize to A. Emerson, 302

Neanderthal Man in Central Asia, Dr. A. Hrdlička, 63

Nebennierenrinde, Die funktion der, Prof. F. Verzár (*Review*), 404

Nebulæ and Star Clusters in the Southern Hemisphere, Dr. H. Shapley and J. S. Paraskevopoulos, 596

Nebular: Red-Shifts, Interpretation of, Dr. K. R. Popper, 69, 701; Spectra, Red-Shifts in, and Scientific Practice, Prof. H. Dingle, 224

Neolithic Trackway, A, Miss C. A. Simpson and Miss Clifford, 153

Neurology, Landmarks in (*Review*), 166

Neurosecretory Cells in the Ganglia of Lepidoptera, M. F. Day, 264

Neurospora, Genetical Investigation in, B. O. Dodge, 309

Neutron, Proton and, Magnetic Moments of, Scattering of Mesons and the, Dr. W. Heitler, 29

Neutrons, Some Biological Applications of, and Artificial Radioactivity, Dr. J. H. Lawrence, 125

Newall Telescope, [1870], 274

Newton's: Inverse Square Law and his use of a False Radius of the Earth, The story of, J. Miller, 158; Knowledge of the Radius of the Earth, 158

New: Guinea: Ethnological Reconnaissance in, J. L. Taylor, 506; Skulls, Age and Sex in, W. D. Hambly, 826; Jersey, Earth Tremors in, Prof. W. A. Lynch, 258; World Order: The, Whether it is Attainable, How it can be Attained, and what sort of World a World at Peace will have to be, H. G. Wells (*Review*), 45; York Hospitals, Mortality in, 892; Zealand: Australia and, Electricity Supply in, 77; Romney Lamb, A Mendelian situation in the Birthcoat of the, Dr. F. W. Dry, P. R. McMahon and J. A. Sutherland, 390; Forest Life of, A Century in the, Dr. E. V. Laing, 943; World Planning, Brave, W. J. Blyton, 966

Nicotiana, Doubling the Chromosomes of, H. E. Warmke and A. F. Blakeslee, 74

Nigeria, Southern, Rain Forest of, Dr. P. W. Richards, 983

Night Sky: in February, 146; in March, 302; in April, 509; in May, 666; in June, 817; in July, 1015; Luminescence, Origin of the Yellow Line in Twilight and the, E. Tönsberg and Prof. L. Vegard, 588

Niobium, Oxides of, G. Brauer, 903

Nitrogen: Excretion from Leguminous Root Nodules, A Factor influencing, Prof. A. I. Virtanen and M. Torniainen, 25; Excretion and Metamorphosis, A. F. Munroe, 268; Tribromide, Schmeisser, 787; Fixation in the Rice-Field Soils of Bengal, Dr. H. Chaudhuri, 936

Non-Ferrous Metallic Ores, Appointment of a departmental committee on, 420

North-East Coast Institution of Engineers and Shipbuilders, election of officers, 701

Norwegian Fauna, 663

Nova Aquilæ (1918), Spectrum of, Dr. A. B. Wyse, 517

Nuclear: Energy-Levels, Series in, Dr. K. M. Guggenheimer, 104; Physics, Further Applications of the Photographic Method in, Dr. C. F. Powell, 155; Forces, The Theory of, Prof. R. Peierls, 687

Nuclei, Stable, Excited States of, Dr. C. F. Powell, A. N. May, Prof. J. Chadwick and T. G. Pickavance, 893

Nucleic Acid, Turnover Rate of, Dr. L. Hahn and Prof. G. Hevesy, 549

Nucleus, A pigmented, Prof. W. A. Beck and R. A. Joly, 226

Nursery Practice, American (*Review*), 762

Nutrition: Milk and, 273; The Newer Knowledge of, Prof. E. V. McCollum, Dr. Elsa Orent-Keiles and Dr. H. G. Day. Fifth edition (*Review*), 816

Nylon Fibre, Artificial, Optics of the, Prof. A. Frey-Wyssling, 821

Observer's Handbook for 1940 (*Review*), 498

Œstrogens, Action of, on the Female Genital Tract, C. W. Emmens and Dr. R. J. Ludford, 746

Oil Engine, H. Akroyd Stuart and the, T. Hornbuckle and A. K. Bruce, 97

Oleaceæ, Floral Anatomy of the, Prof. A. C. Joshi and A. N. Fotidar, 354

Olive Tree, Rooting of the, J. V. Natividade, 632

Ophiobolus graminis, Utilization of Nitrogen by, S. D. Garrett, 108

Optical Anisotropy of Cellulose Sheet, Dr. R. C. Gray, 266

Orchis Tubercles, B. C. Sharman, 192

Ordnance: and Gunnery, Prof. H. C. Plummer (*Review*), 443; Elements of, a Textbook for use of Cadets of the United States Military Academy, prepared under the direction of Lt.-Col. T. J. Hayes (*Review*), 443

Orthogonal Polynomials, Prof. G. Szegö (*Review*), 139

Osage Warfare, late F. La Flesche, 33

Ottawa, Electricity and Gas Inspection Services in, 159

Ova, Artificially Activated, Offspring from, S. Pincus, 33

Oxford: Early Science in, Dr. R. T. Gunther. Vol. 11: Oxford Colleges and their Men of Science (*Review*), 282; University: H. G. Champion appointed professor of forestry, 19; Dr. E. G. T. Liddell appointed Waynflete professor of physiology, 292; Early Botany at, Dr. J. Ramsbottom, 993

Oxide Films on Alloy Steels, Dr. A. G. Quarrell, 821

Oxygen Administration and Inhalation Apparatus, 508

Oxy-hydrogen Light, Use of, [1870], 80

Oyster Beds, British, Effect of the Severe Winter of 1939–40 on, H. A. Cole, 976

Ozone and some Compounds, Structures of, C. L. Lewis and C. P. Smyth, 35

Pacific Basin, Structure of the, B. Gutenberg, 269

Pages from the Past, H. A. L. Fisher (*Review*), 683

Painting, Forgotten methods of, H. Hubbard, 256

Palæolithic Man in the North Midlands, A. Leslie Armstrong (Wilde Memorial Lecture), 78

Palæontologist, Some Memories of a, Prof. W. Berryman Scott; Sir A. Smith Woodward (*Review*), 121

Palæontology, Applications of Statistics to, D. Leitch, 1026

Palao Tropical Biological Station, The, Prof. C. M. Yonge, 16

Palladium, Diffusion in, Dr. R. M. Barrer, 898

Paper: Dr. J. Grant (*Review*), 327; and its Uses: a Treatise for Printers, Stationers and others, E. A. Dawe. Vol. 1, fourth edition; Vol. 2: Samples of Papers and Boards (*Review*), 327

Paramecium, 3:4-Benzpyrene, and the Production of Tumours, J. C. Mottram, 184

Paris: Academy: of Medicine, award of the Jansen prize to Prof. A. Bessemans, 66; of Sciences, prize awards of the, 101; Observatory, [1870], 198; 235; Academy of Medicine, Dr. L. Martin elected president of the, 346

Parliamentary and Scientific Committee of the House of Commons: Capt. L. F. Plugge elected chairman of the, 20; 216; election of officers, 460

Parthenocarpy, S. Yasuda, 826

Pathogen, A Beneficial, S. H. Ou, 675

Patterson Projection of the Skeletons of the Structure Proposed for the Insulin Molecule, Dr. Dorothy Wrinch, 1018

Pea: Garden, Genetics of the, C. Pellew, 751; Sweet, Linkage Group in the, Prof. R. C. Punnett; Dr. C. D. Darlington, 1025

Peace-making after War, Lord Eustace Percy, 610

Pears, Classification of, M. B. Crane and D. Lewis, 942

Pearson, Karl, A Bibliography of the Statistical and other Writings of, compiled by G. M. Morant with the assistance of, B. L. Welch (*Review*), 1010

Peirce's, Charles, Empiricism, Dr. J. Buchler (*Review*), 1010

Pennsylvania University, Impending bicentenary of, 931

Pepsin, Hydrolysis of Proteins by, A. Tiselius and I.-B. Eriksson-Quensel, 193

Perch Pituitary, The Herring Material in the, T. Kerr, 591

Periodicities, Reality of, Dr. H. R. Hulme, 979

Permian System, C. O. Dunbar, 786

Peroxidases, Dioximaleic Acid Oxidase Action of, Dr. B. Swedin and Prof. H. Theorell, 71

Personality: Psychological Foundations of, a Guide for Students and Teachers, Prof. L. P. Thorpe (*Review*), 140

Peru: Mental Disease in, Dr. H. M. Pollock, 144; Travels in (*Review*), 685

Pest: Infestation of Produce, 968; Control Chemicals, 1013

Petrography: Sedimentary, Manual of, 1: W. C. Krumbein; 2: F. J. Pettijohn (*Review*), 85; of the Igneous Rocks, A Descriptive, Vol. 1, Prof. A. Johannsen. Second edition (*Review*), 1007

Pharmaceutical Society: award of the Harrison lectureship medal to A. D. Powell, 66; election as honorary members of Col. Ram Nath Chopra, Sir Ernley Blackwell and Sir William Willcox, 736

Pharmacopœia Revision, Dr. C. H. Hampshire, 583

Pharmacy, Authorization of Faculties in, in French Universities, 931

Phenyl *Iso*cyanate, Inactivation of Prolactin by Treatment with, A. C. Bottomley and Dr. S. J. Folley, 304

Philippines, Life Expectancy in the, A. G. Sison, H. Lara, M. M. Herbosa and A. A. Lozano, 967

Phonetics, Experimental, Recent work in, Dr. E. G. Richardson, 841

Phosphorus: Pentachloride, Crystal structure of, H. M. Powell, D. Clark and Dr. A. F. Wells, 149; Pentabromide, Crystal structure of, H. M. Powell and D. Clark, 971

Photo-cell Applications in the Foodstuffs Industries, A. Seymour, 1014

Photochemistry: Dr. H. W. Melville (*Review*), 609; and the Mechanism of Chemical Reactions, Prof. G. K. Rollefson and Dr. M. Burton (*Review*), 609

Photodynamic Hæmolysis by Carcinogenic Hydrocarbons, M. Wolman, 592

Photographic: Method in Nuclear Physics, Further Applications of the, Dr. C. F. Powell, 155; Material used in Astronomy, Sensitometry of, D. R. Barber, 787

Photographie: Wissenschaftliche, eine einführung in Theorie und Praxis, Prof. E. v. Angerer. Zweite Auflage (*Review*), 142

Photography: Applications of, to Engineering, A. H. Styring, 397; its Principles and Practice: a Manual of the Theory and Practice of Photography, C. B. Neblette. Third edition (*Review*), 501

Photosynthesis, Mechanism of, K. Wohl, 983

Phycomycetes, Predaceous, from Cotswold Leaf-mould, C. L. Duddington, 150

Phyla of Organisms, Keys to the, including Keys to the Orders of the Plant Kingdom, Dr. F. A. Barkley (*Review*), 494

Phylogeny and Taxonomy, J. S. L. Gilmour and others, 636

Physical Society, Proceedings of the, resignation of Capt. C. W. Hume of the editorship of the, 180

Physical: Apparatus, New, Prof. C. J. Overbeck, 219; Science: and Free Will, Principles in, Prof. E. Schrödinger (*Review*), 402; The Philosophy of, Sir Arthur Eddington, (Tarner lectures), (*Review*), 402; Society, award of the Duddell medal to Prof. E. O. Lawrence, 852

Physicists, Training, 65

Physics: of the Earth, 8: Terrestrial Magnetism and Electricity, edited by J. A. Fleming (*Review*), 47; in War, Prof. M. L. E. Oliphant, 299; Institute of, and Freedom in Science, 345; in the Glass Industry, Prof. W. E. S. Turner, 446; Theoretical, Aspects of, Prof. Max Born (*Review*), 528; Fun and, Prof. J. A. Crowther (*Review*), 567; and Engineering, New Units in, Suggestions for, 597; Atmospheric and Terrestrial (*Review*), 760; Progress in, Reports on, Vol. 6. General Editor: J. H. Awbery (*Review*), 797; The Progress of, Prof. J. A. Crowther (*Review*), 797; Theoretical, Considerations concerning the Fundaments of, Prof. A. Einstein, 920; Household, W. G. Whitman. Third edition (*Review*), 1009

Physik: chemischen, Hand- und Jahrbuch der: Herausgegeben von A. Eucken und K. L. Wolf. Band 10, Abs. 3: Starkeffekt, B. Mrowka; Elektrischer Kerr-Effekt, Dr. H. A. Stuart (*Review*), 294; Band 3, Teil 2, Abs. 3–4 (*Review*), 528; theoretischen, Lehrbuch der, Prof. G. Joos. Dritte Auflage (*Review*), 528

Pineal Gland, The Nerve of the, Prof. W. E. Le Gros Clark, 349

Pisum sativum, Genetical Sterility in, Mrs. E. R. and Dr. F. W. Sansome, 226

Pithecanthropus and Sinanthropus, The Relationship between, Prof. W. E. Le Gros Clark, 70

Pittsburgh University, D. C. Bradford appointed seismologist at, 892

Plankton: Investigations in the Java Sea, Preliminary, Dr. H. C. Delsman, 41; Cultures, Large-Scale, H. Pettersson, F. Gross and F. Koczy, 698

Plant: Virus Diseases (*Review*), 122; Viruses and Virus Diseases, F. C. Bawden (*Review*), 122; Life, The World of, Prof. C. J. Hylander (*Review*), 136; Alkaloids, The, Dr. T. A. Henry. Third edition (*Review*), Dr. W. H. Linnell, 243; Viruses, Recent American work on, 518; Hunting through the Centuries, F. Kingdon Ward, 574; Personalities, J. S. L. Gilmour (*Review*), 608; Viruses, Some Effects of Salicylate on, R. J. Best, 627; Respiration, Salt Accumulation and, R. N. Robertson, 937

Plants: Salt Absorption of, Prof. H. Lundegårdh, 114; Prof. D. R. Hoagland and Dr. F. C. Steward, 116; Intergrading among, in relation to the Provenance of Forest Trees, Dr. R. Melville, 130; Growth Behaviour of, following Seed Treatment by Organic Mercury Compounds, Dr. G. R. Bates, 262; Economic Structure of, Prof. H. E. Hayward (*Review*), 293; with Personality, P. M. Synge (*Review*), 608

Platypus, Undercoat of the, Prof. A. F. Barker, 186

Pleistocene and Prehistory in Europe and China, Wen-Chung Pei, 516

Point Dipoles, Classical Theory of, Dr. H. J. Bhabha, 819

Poisonous Snake Harmless, A New Method of Rendering a, D. B. Jaros, 1025

Polar Exploration, Carbon Monoxide as a Hazard of, Prof. Yandell Henderson and J. McCullough Turner, 92
Polynesian Economy, Primitive, Prof. R. Firth (*Review*), 328
Postage on printed matter, [1870], 599
Potassium : from Muscle, Liberation of, by Acetylcholine, V. H. Cicardo and J. A. Moglia, 551 ; and Muscle Contraction and its absence after Adrenalectomy, Prof. F. Verzár and J. C. Somogyi, 781 ; Metabolism, Thyroid Gland and, Prof. I. Abelin, 935
Potato Blackleg, Bacterium causing, Identity of the, Dr. W. J. Dowson, 263
Potatoes in War-time, 62
Power, The Development of, E. C. Wittick (*Review*), 281
Prawn, Common, Osmotic properties of the, N. Kesava Panikkar, 108
Prehistoric Peoples in South Africa, Prof. M. R. Drennan, 394
Primula kewensis, Genetics of, M. Upcott, 154
Primula vulgaris, Populations of, High Proportions of Homostyle Plants in, J. L. Crosby, 672
Primus Stove at High Altitudes, The, P. J. H. Unna, 190
Probability : Integral, The, late W. F. Sheppard (Mathematical Tables, Vol. 7) (*Review*), 139 ; and its Applications (*Review*), 167 ; Statistics and Truth, Prof. R. von Mises. Translated by J. Neyman, D. Sholl and E. Rabinowitsch (*Review*), 167 ; Theory of, Dr. H. Jeffreys ; M. G. Kendall (*Review*), 607
Procrustes, the Bed of, G. D. Knox, 585
Producer Gas for Motor Vehicles, 473
Professional Civil Servants, Institution of, Twenty-first annual report of the, 927
Prolactin, Inactivation of, by Treatment with Phenyl *Iso*cyanate, A. C. Bottomley and Dr. S. J. Folley, 304
Prostitutes, Adult, Rehabilitation of, 218
Proteins, Glutamic Acid of, Prof. A. C. Chibnall, M. W. Rees, E. F. Williams and Dr. E. Boyland, 311 ; Dr. A. Konikova ; Dr. B. W. Town, 312 ; in Egg-White, Native State of, Prof. E. Gordon Young, 1021
Proton : and Neutron, Magnetic Moments of, Scattering of Mesons and the, Dr. W. Heitler, 29 ; attracting Properties of Liquids, Gordy and Stanford, 633
Protons : Bombardment of Nitrogen and Oxygen with, S. C. Curran and J. E. Strothers, 224 ; Diffraction of, by Vapours, H. J. Yearian, 431
Prunus triloba, Shoot Wilt of, W. C. Moore, 153
Psusennes : Treasure of, 418 ; Tomb of, at Tanis, 584
Psychic Phenomena, Laboratory Investigations into, H. Carrington (*Review*), 501
Psychoanalysis : New Ways in, Dr. K. Horney (*Review*), 500 ; Dr. E. Glover (*Review*), 662
Psychological Issues : Selected Papers of Prof. Robert S. Woodworth. With a Bibliography of his Writings (*Review*), 989
Psychology : of the Initiate, C. P. Mountford, 63 ; Applications of, in War Conditions, 174 ; General, J. P. Guilford (*Review*), 298 ; and Educational Research, Dr. D. D. Shendarkar, 522 ; A Pioneer in (*Review*), 989
Psychopathic States, Prof. D. K. Henderson (Thomas W. Salmon Memorial Lectures) (*Review*), 140
Public : Health in War-time, Sir Arthur MacNalty (Chadwick lecture), 315 ; Instruction, Minister of, [1870], 318
Puerperal Sepsis, Control of, 112
Puffin crosses North Atlantic, 773

Quanta, Heavy, Theory of, F. J. Belinfante (*Review*), 500
Quantitative : Characters, L. Powers, 154 ; Inorganic Analysis : a Text-Book of, Theory and Practice, Dr. A. I. Vogel (*Review*), 495
Quantum Mechanics : Lectures on, Prof. M. Raziuddin Siddiqi. Vol. 1 (*Review*), 528 ; New Method in, Dr. E. Schrödinger, 712
Quartz, The α–β Transformation of, Sir C. V. Raman and T. M. K. Nedungadi, 147 ; Prof. H. S. Allen, 306
Quetta Earthquake of 1935, K. R. Ramanathan and S. M. Mukherji, 393

Rabbit : Coprophagy in the, Dr. A. Eden, 36 ; Wild, Coprophagy in the, H. N. Southern, 262 ; Ova, Induction of, Polyploidy in, G. Pincus and C. H. Waddington, 595 ; Coprophagy in the, Origin of 'Night' Fæces, Dr. A. Eden, 628 ; Control, Some Experiments in, R. M. Lockley, 767
Race, Language and Culture, Prof. F. Boas (*Review*), 951
Radiation Worker, Protection of the, Dr. G. W. C. Kaye (Stanley Melville memorial lecture), 370
Radioactive Standards, 456
Radioactivity, Artificial, Some Biological applications of Neutrons and, Dr. J. H. Lawrence, 125
Radio : Interference Suppression, G. W. Ingram (*Review*), 137 ; Waves, Propagation of, along the Earth, Dr. J. S. McPetrie and Miss A. C. Stickland ; Dr. J. S. McPetrie and J. A. Saxton, 234 ; Transmission, Scattering of Waves in, T. L. Eckersley, 317 ; Transmitter, New, 418 ; -Sulphur, Dr. H. Levi, 588 ; Frequency Wave Guides, Dr. J. E. Houldin, 792 ; Therapeutic Panel of Physicists, Constitution of a, 928
Radium : Treatment : Sir Leonard Hill, 151 ; Prof. S. Russ ; Prof. A. S. Eve, 347 ; and Radon Therapy, Physical Aspects of, C. E. Eddy and T. H. Oddie. Second edition, 864 ; Medical uses of, 941
Radon, Radium and, Therapy, Physical aspects of, C. E. Eddy and T. H. Oddie. Second edition, 864
Rain Forest of Southern Nigeria, Dr. P. W. Richards, 983
Raman : Effect, The, and its Chemical Applications, Dr. J. H. Hibben ; with a Theoretical Discussion by J. H. Hibben and Prof. E. Teller (*Review*), 406 ; Spectra of Co-ordination Compounds, J. P. Mathieu, 675
Random Sampling Numbers, Tables of, M. G. Kendall and B. Babington Smith (*Review*), 1010
Raspberry Mosaic, R. V. Harris, 556
Rat, the Black, in Great Britain, C. Matheson, 416
Rats : Adrenalectomized, Cozymase in, Prof. J. Runnström, E. Sperber and E. Bárány, 106 ; Hypophysectomized, Effect of Stilbœstrol on the Ovaries of, P. C. Williams, 388
Ray Society, election of officers, etc., 416
Reading University, Dr. Barbara Colson appointed lecturer in botany, 523
Real Variable, Theory of Functions of a, An Introduction to the, S. Verblunsky (*Review*), 296
Reconstruction : in Europe, 1 ; A Ministry of, 681
Refractor, A Great, [1870], 118
Regional Organization during and after the War, Brig. Sir Edward Tandy, 697
Relativity : The Mass Centre in, Prof. Max Born and K. Fuchs, 587 ; of Time, Dr. F. C. Powell ; Prof. H. Dingle, 626 ; Mass Centre in, Prof. A. D. Fokker ; Prof. Max Born and K. Fuchs, 933
Reproduction, Metabolism of, Carotenoids and the, R. Emerson and D. L. Fox, 594
Research : Direction and Utilization of, 81 ; the Planning of : Lord Chatfield, 399 ; Prof. W. F. K. Wynne-Jones, 417 ; Experimental, and Unemployment, [1870], 637 ; and Invention in Universities, 639
Respiration at Sub-optimum Substrate Concentrations, Inhibition of, W. F. Floyd, 592
'Rhizosphere', The, A. G. Lochhead, 711
Rhodes-Livingstone Institute, Work of the, Godfrey Wilson, 255
Rhodes Scholarships : Statement of the, 1938–39, 65 ; for India, 417
Rhodesia : Southern, Meteorology of, 99 ; Ancient Gold-working site in, Neville Jones, 430
Rhododendron Complex, A, J. M. Cowan, 978
Rice, Nutritive Value of, Dr. W. R. Aykroyd, 522
Risso's Grampus in the Mersey, Supposed, 64
River : A Forgotten, a book of Peruvian Travel and Botanical Notes, C. Sandeman (*Review*), 685
Road : Surface Texture, A Printing Method of recording, 40 ; Research Laboratory, Report of the, 561 ; Obstruction Lanterns, 1014
Roads with a Cotton Fabric Basis, 699
Rockefeller Foundation : Prof. W. W. Stewart elected chairman and member of the board of the, 586 ; The, a Review for 1939, Dr. R. B. Fosdick (*Review*), 833

Rock: -Drawings of Southern Upper Egypt. I: Sir Robert Mond Desert Expedition, Season 1936–1937; Preliminary Report, Dr. H. A. Winkler (*Review*), 84; Metamorphism, Prof. H. H. Read (*Review*), 644; -Paintings in South Africa: More, from the Coastal Belt between Albany and Piquetberg. Mainly copied by Joyce and Mollie van der Riet. With Notes, etc. by Miss Dorothea F. Bleek; Abbé H. Breuil (*Review*), 992
Rocksalt, Blue: Dr. J. Newton Friend and J. P. Allchin, 266; Dr. H. Pettersson, 743
Rocks and Ores, Oxygen Isotopes in, M. Dole and R. L. Slobod, 751
Roman Town in East Yorkshire, A, P. Corder and Rev. Thomas Romans, 272
Rome University, award of the Ettore Marchiafava prize to Prof. M. Monacelli, 586
Rona: A Naturalist on, Essays of a Biologist in Isolation, Dr. F. Fraser Darling (*Review*), 810
Rose, A New Species of, B. O. Mulligan, 467
Roses, A book of, Dr. J. Ramsbottom (*Review*), 136
Rossi Transition Curve for Copper, The Second Maximum in the, P. J. G. de Vos, 387
Rostro: -Carinate Stone Implement from Rhodesia, Neville Jones, 467; -carinates in Africa, H. B. S. Cooke and J. D. Clark, 902
Rothamsted Experimental Station, E. J. Roberts, 76
Royal: Academy, 1940, Science in the, Lieut W. E. Swinton, 730; Aeronautical Society: election of officers, 892; gift to the, by Mrs. G. Alston for a Peter Alston memorial prize, 931; Air Force, Education in the, 618; Asiatic Society, award of the University prize to A. Briggs, 259; Astronomical Society: award of the gold medal of the, to Dr. E. Hubble, 95; election of officers, 259; College of Surgeons: of England, Sir Humphry Rolleston, Sir Thomas Dunhill and Sir Hugh Devine admitted honorary fellows of the, 146; award of the John Hunter medal and triennial prize to Dr. L. E. H. Whitby, 460; Geographical Society, awards of the, 665; Institute of Public Health and Hygiene, award of the Harben gold medal to Sir Leonard Hill and of the Smith award to Sir William Savage, 259; Irish Academy, Dr. E. Schrödinger appointed professor of Theoretical Physics in the, 544; Meteorological Society: award of the Symons gold medal to Dr. J. Bjerknes, 19; Phenological Report for 1939, 698; Society: New fellows of the, 455; election as foreign members, of Maurice, Duc de Broglie, Prof. R. G. Harrison, Prof. G. N. Lewis and Dr. F. P. Rous, 851; of London for the Promotion of Natural Knowledge, The Record of the. Fourth edition (*Review*), 873; Progress of the, Dr. J. I. O. Masson (*Review*), 873; of Edinburgh: election of fellows, 384; award of the Keith prize to Prof. F. A. E. Crew and of the Neill prize to J. Wright, 385; Botanic Garden, Calcutta, Dr. K. Biswas, 959; Observatory, Greenwich: Annual Report of the Astronomer Royal, 980; Meteorological Society, award of the Howard prize to Cadet S. R. Pryor, 1015; Academy, Natural Science at the, [1870], 1030
Rubber: Softening of, V. H. Wentworth and J. D. Hastings, 34; at Low Temperatures, Heat Conductivity of, A. Schallamach, 67; Paving Block, New type of, 891
Rubus Aphides, Biology of, G. H. L. Dicker, 978
Rumex acetosella L., Polyploidy in, Askell Löve, 351
Rural Life in Europe, Dr. L. Dudley Stamp, 356
Rusts, Crossing Experiments with, T. Johnson and Margaret Newton, 786
Rutherford: Dr. C. G. Darwin (*Review*), 324; Being the Life and Letters of the Rt. Hon. Lord Rutherford, O.M., Prof. A. S. Eve (*Review*), 324
Ryegrass, Blind Seed Disease of, Dr. M. Wilson, M. Noble and E. G. Gray, 783

Sabouraud, Raymond. work of, Dr. L. Grigoraki, 968
Salicylate, Some Effects of, on Plant Viruses, R. J. Best, 627
Saliva Superstitions, Miss Rachel Sclare, 585
Salt: Absorption of Plants, Prof. H. Lundegårdh, 114; Prof. D. R. Hoagland and Dr. F. C. Steward, 116; Deposits, Prof. H. H. Read (*Review*), 279; Accumulation and Plant Respiration, R. N. Robertson, 937
Salts, Calcium and Strontium, Flame and Arc Spectra of some, Prof. R. K. Asundi and Dr. B. K. Vaidya, 224
Salvage and Utilization of Waste, 988, 1012
Sandal, 'Spike' Disease of, Control and Eradication of New Outbreaks of the, Rao Sahib S. Rangaswami and A. L. Griffith, 754
Sargassum Weed, Biology and Systematics of the, A. E. Parr, 559
Scabies, Memorandum on, 548
Scandinavia, Present Conditions in, 582
School Child, Health of the, Sir Arthur MacNalty, 255
Science Abstracts, 460
Science: Islam's Contributions to, Dr. E. J. Holmyard (*Review*), 4; and Scientists, Position of, in the War Situation, Prof. H. Levy and others, 61; Government aid to, [1870], 80; and Educational Policy, 119; and War, Dr. V. Bush, 143; and Everyday Life, Prof. J. B. S. Haldane (*Review*), 201; for a New Audience, J. Langdon-Davies (*Review*), 201; The Public Relations of, Prof. Wesley C. Mitchell, 207; Royal Commission on, [1870], 235; Oxford Men of (*Review*), 282; War and Reconstruction, Dr. J. S. Huxley, 289; General, The Theory and Practice of, H. S. Shelton (*Review*), 297; Forthcoming Books of, 502; Masters' Association, Report for 1939, 548; A Skeleton History of, Prof. A. Wolf (*Review*), 570; since 1500: a Short History of Mathematics, Physics, Chemistry, Biology, H. F. Pledge (*Review*), 570; and Civilization, Dr. B. Lovell (*Review*), 661; Descriptive and Predictive, Sir Richard Gregory, Bart. (*Review*), 722; To-day and To-morrow, Dr. W. Kaempffert (*Review*), 722; in the Royal Academy, 1940, Lieut. W. E. Swinton, 730; International Spirit in, 736; The Growth of, an Outline History, A. P. Rossiter (*Review*), 814; Museum, Dr. H. Shaw appointed acting director of the, 817; Practical, in Schools, 835; and the War Effort, 986; Practical, in Schools, Dr. V. J. Chapman; the Editors of NATURE, 1023
Scientific: and Technical Books, Recent, January 27, iii; February 24, iii; March 30, vii; April 27, iii; May 25, iii; June 29, iii; Centenaries in 1940, Eng.-Capt. Edgar C. Smith, 9; Man-Power, Utilization of, 43; Workers and the Armed Forces, 61; Workers and the War, 61; and Technical Literature and Information, Col. L. Newcombe, 109; the Writer of the Article, 110; Research during the War, Utilization of, Lord Chatfield, 143; Workers and the Armed Forces, Dr. W. A. Wooster, 152; Planning of Local Government, 161; Collaboration between Britain and France, 179; Research for the Services, 179; Management in Administration, 275; and Learned Societies of Great Britain and Ireland, Official Year Book of the, fifty-sixth annual issue (*Review*), 297; Co-operation, British and French, 299; Journals, Censoring, A Panel to assist in, 300; Workers, Government Recruitment of, Dr. W. A. Wooster, 630; Research and Taxation, 696; and Industrial Research: The Department of, Twenty-fifth anniversary, 726; Education, [1870], 793; Films in War-time, 927; Research, Agriculturists and, [1870], 984
Sclerostachya fusca, Chromosome Numbers in, E. K. Janaki-Ammal, 464
Scottish Ethnology, Scandinavian Influence in, Prof. R. A. Fisher and G. L. Taylor, 590
Screw Propulsion, First Twenty Years of, 1838–1858, Eng.-Capt. E. C. Smith, pt. 2, 181
Sea: Work of the, [1870], 235; Fisheries of Europe, 432
Sediments, Mechanical Analysis of (*Review*), 85
Sedov, Drift of the, 145; Prof. N. N. Zubov, 533
Seed: Dressings, Growth Hormones in, H. E. Croxall and L. Ogilvie, 516; Disinfection, W. A. R. Dillon Weston and C. C. Brett, 824
Seedlings in Transit, New Method of, 219

Seeing at Night, R. G. Hopkinson, 458
Seismograph Stations, Density of, H. Landsberg, 675
Seismology, Bibliography of, 13, No. 2, 24
Selenium-containing Plants, Toxicity of, to Pests, V. H. Morris, C. R. Neiswander and J. D. Sayre; Neiswander and Morris, 430
Sĕnoi (Sakai), lowland, Vital Statistics of the, H. D. Noone, 97
Sequoia sempervirens, Gynospore Formation in, Prof. J. Doyle, 900
Seventy Years Ago, 41; 80; 118; 160; 198; 235; 274; 318; 360; 398; 436; 474; 523; 561; 599; 637; 679; 717; 755; 793; 831; 869; 908; 946; 984; 1030
Sex: and Internal Secretions: a Survey of Recent Research. Editor: E. Allen. Second edition (*Review*), 662; A Great Psychologist of, Prof. J. C. Flugel (*Review*), 759
Sexes, Outbreeding and Separation of the, Dr. K. Mather, 484
Shamanism in the South-West United States, Isabel T. Kelly, 941
Shape of Things: The, an Introduction to Design in Everyday Life, N. Carrington (*Review*), 82
Sheep, Pining in, not Curable by Cobalt Administration, W. Lyle Stewart and Dr. A. Phyllis Ponsford, 1023
Sheffield University: Dr. W. Sucksmith appointed professor of physics, 776, 887; impending retirement of Prof. S. R. Milner, 887
Sherrington, Sir Charles, Selected Writings of, Compiled and edited by Dr. D. Denny Brown (*Review*), 166
Shining in Human Eyes, D. G. A. Dyson, 737
Shoshoni Indians, Cultural change Among, J. H. Steward, 192
Sidmouth: The Scenery of, its Natural Beauty and Historic Interest, Dr. Vaughan Cornish (*Review*), 1006
Significance: Tests of, What they Mean and How to Use Them, J. H. Smith (*Review*), 1010
Silicosis: Causation of, F. W. Simson and A. S. Strachan, 631; Aluminium Dust in, L. H. Germer and K. H. Storks, 941; Disease in the South Wales Coalfield, 968
Silver Halides, Optical Sensitizing of, by Dyes, Dr. S. E. Sheppard, R. H. Lambert and R. D. Walker, 969
Sinanthropus, Pithecanthropus and, The Relationship between, Prof. W. E. Le Gros Clark, 70
Singing, Art of, The Physiological Basis of the, H. Hemery (*Review*), 816
Sirius and the Constellation of the Bow, Dr. H. Chatley, 670
Skeletal Muscle, A Crystalline Albumin Component of, Dr. K. Bailey, 934
Sky Blue ?, Why is the, [1870], 717
Smith, William, Father of English Geology, Life and work of, Dr. L. R. Cox, 299
Smithsonian Institution: Prof. H. Arctowski at work in the, 544; Report for year ended June 30, 1939, 930
Smoke Abatement in War-time, 419
Smut Disease, Loose, Control of, G. Howard Jones, 34
Snake Bite, Treatment for, [1870], 41
Snakes, Moulting in, R. M. Stabler, 309
Snake's Venom, Toxicity of, N. O'Connor Wolff and T. S. Githens, 392
Snow: on Solids, Angle of Repose of, R. Schnurmann, 553; and Glaciers, New International Commission of, F. E. Matthes, 753
Snow Cruiser, The Antarctic, 772
Snowfall in the winter of 1939–40, L. C. W. Bonacina, 554
Soaring Flight, The Art of, W. Hirth. Translated by Naomi Heron Maxwell (*Review*), 142
Social Organism, The, A. H. Mackmurdo, 187
Socialism, Victorian, Dean Inge (*Review*), 45
Soil: Organic Matter, Town's Refuse as a Source of, Dr. E. H. Tripp, 56; Fertility, Some Biological Aspects of, Prof. W. Neilson Jones, 411; Analysis: a Handbook of Physical and Chemical Methods, C. H. Wright. Second edition (*Review*), 1004
Soja, Le, et les industries du soja: produits alimentaires, huile de soja, lecithine végétale, caséine végétale, A. Matagrin (*Review*), 48
Solar: Eclipse, Total, of October 1, 1940, Prof. F. J. M. Stratton, 32; Spots, On the Periodicities of the, [1870], 80; *D* lines, Photometry of the, C. W. Allen, 353; Eclipse of October 1, 1940, 712; Spectrum, Alpha Photometric Observations of the, D. S. Evans, 787; and Terrestrial Relationships of March 23–29, 1940, M. A. Ellison, 898; Ultra-Violet, Energy in the, E. Pettit, 1026
Solubility, Solvent Effect on, T. W. Davis, J. E. Ricci and C. G. Sauter, 310
Solutions, Surface of, Prof. J. W. McBain, W. V. Spencer, J. R. Vinograd and D. A. Wilson, 786
Somaliland, French, Volcanism in, E. A. de la Rüe, 828
Somatic Tissue, Translocation in the, L. V. Morgan, 309
South Africa: Malnutrition in, Ellen Radloff and T. W. B. Osborn, 22; Prehistoric Peoples in, Prof. M. R. Drennan, 394; Union of, Road Accidents in the, 968
South African: Native Policy and the Liberal Spirit, Prof. R. F. A. Hoernlé (Phelps-Stokes lectures), 564; Institute for Medical Research, Dr. E. H. Cluver appointed director of the, 1015
South Australia, Primitive Insects of, H. Womersley, 967
Southward: This Way, the Account of a Journey through Patagonia and Tierra del Fuego, A. F. Tschiffely (*Review*), 811
South-West Essex Technical College, Report for 1938–39, 775
Sovereigns, Sweating, [1870], 118
Soya Bean, The, Sir Geoffrey Evans (*Review*), 48
Space, Spanning, C. A. Claremont (*Review*), 281
Special Libraries and Information Bureaux, Association of, Annual Report of the, 314
Spectrograph Coils, Magnetic, M. Ference, A. E. Shaw and R. J. Stephenson, 596
Spectroheliosсope: Use of Monochromatic Image in the, M. A. Ellison, 154; An Auto-collimating, M. A. Ellison, 517
Spectroscopy: Chemical, Prof. W. B. Brode (*Review*), 568; Chemical Applications of, Dr. W. Rogie Angus (*Review*), 568
Spencer: Herbert, Betrayed, with some account of the Repudiation of the "Descriptive Sociology" by his Trustees, A. W. Tillett (*Review*), 493
'Spike' Disease of Sandal, Control and Eradication of New Outbreaks of the, Rao Sahib S. Rangaswami and A. L. Griffith, 754
Spiritual Values and World Affairs, Sir Alfred Zimmern (*Review*), 439
Splashes, and What They Teach, Prof. Allan Ferguson (Alexander Pedler lecture), 508
Sponges, Pigments of, Dr. P. J. Drumm and W. F. O'Connor, 425
Spreading Factors, Natural and Artificial, Mucolytic Effect of, 866
Stability, Distributional, Dr. A. Wintner, 225
Stainless Steels, Oxide Film on, T. Tokumitu, 589
Stamps, Commemorative, to American Science, 964
Star: -streams, Constants of the, Dr. W. M. Smart and T. R. Tannahill, 310; Clusters, Moving, Criteria of, Dr. W. M. Smart, 556; Atlas, A, and Reference Handbook (Epoch 1920–1950): for Students and Amateurs, A. P. Norton (*Review*), 656
Stars: Surface Temperatures of the, Prof. W. M. H. Greaves, 412; Relative Gradients of 250, determined at the Royal Observatory, Greenwich, Dr. H. Spencer Jones, 865
Starch from Glucose-1-Phosphate, Enzymic Synthesis of, C. S. Hanes, 348
Starling, Female (*Sturnus v. vulgaris,* L.), Male Behaviour of the, in Autumn, Dr. W. S. Bullough and Dr. R. Carrick, 629
Statesman's Year-book, 1940. Edited by Dr. M. Epstein (*Review*), 1006
Statistical: Methods, Modern, An Introduction to, P. R. Rider (*Review*), 296; Methods and Ethnographical Observations, Prof. A. L. Kroeber, 300; Mathematics, Dr. A. C. Aitken (*Review*), 1010; Methods: for Medical and Biological Students, Prof. G. Dahlberg (*Review*), 1010

Statistics : Teaching of, Dr. J. Wishart, 99 ; and Engineering Practice, Dr. B. P. Dudding and W. J. Jennett, 117
Stearanilide, Hydration of, B. A. Toms, 227
Steinsalz und Kalisalze : Geologie, Prof. F. Lotz (*Review*), 279
Stellar System, Absorption within the, J. Stebbins, C. Hugger and A. Whitford, 675
Stereo Plate Casting, Progress in, 700
Stilbœstrol, Effect of, on the Ovaries of Hypophysectomized Rats, P. C. Williams, 388
Stoic, The, April, 817
Stomatopoda from the John Murray Expedition, B. Chopra ; G. E. H. Foxon, 750
Stove, Wood-burning, New Type of, 218
Strange Noises heard at Sea off Grey Town, [1870], 755
Strata, Orientation of, First Use of Current-Bedding to Determine, Dr. A. Lamont, 1016
Straw, Soil Decomposition of, T. S. Sadasivan, 596
Streptocarpus, The genus, W. J. C. Lawrence, 269
Structure and Function (*Review*), 244
Sugar : in Fermentation, Decomposition of, [1870], 274 ; -Cane, Smut Fungi of the, Dr. B. B. Mundkur, 827
Sulphanilamide and Glucose Antidote, Dr. Matilda M. Brooks, 707
Sulphathiazole in the Treatment of Pneumonia, 112
Sulphur, Liquid and Plastic, X-Ray Diffraction of, Gingrich, 751
Sulphuryl and Thiophosphoryl Fluorides, Structures of, D. P. Stevenson and H. Russell, 393
Sunday Lectures, [1870], 436
Sunspot, A Big, 509
Sunspots, Big, 66
Sun's Speed of Galactic Rotation, G. L. Camm, 230
Supernovæ, New, Dr. J. Johnson, 827
Supply, Ministry of, J. Davidson Pratt appointed an additional director-general for chemical research, experiment and development in the, 931
Surnames, Intelligence and Fertility, Dr. J. A. Fraser Roberts, 939
Suspensions : Rheology of, a Study of Dilatancy and Thixotropy, H. L. Röder (*Review*), 499 ; Viscosity of, and the Einstein Equation, Dr. E. W. J. Mardles, 970
Sutton Hoo : Ship Burial, Antiquities from the, T. D. Kendrick and others, 231 ; Burial a Cenotaph ?, 343 ; Ship-burial, Articles in *Antiquity* on, 585
Sweat, Inheritance of Inability to, L. C. Glass and D. H. Yost, 353
Sweet Potato Breeding, J. C. Miller, 353
Swimming Baths, Hygiene of, Dr. M. Mazillier, 738
Swiss Watch-making Industry, 100

Takoradi, New Government Technical School at, 545
Tanganyika Territory, a Field Key to the Savanna Genera and Species of Trees, Shrubs and Climbing Plants of, late B. D. Burtt, 750
Tata, Lady, Memorial Fund, Awards from the, 968
Taxonomy : Experimental, J. W. Gregor, 392 ; Phylogeny and, J. S. L. Gilmour and others, 636
Teak Defoliators, Biology of Parasites of, P. F. Garthwaite and M. H. Desai ; C. F. C. Beeson and S. N. Chatterjee ; P. N. Chatterjee, 710
Teart Disease in Cattle, W. S. Ferguson, A. H. Lewis and S. J. Watson, 941
Teeth, Front : in Man, Removal of, Dr. A. Hrdlička, 631 ; Evulsion of, in East Africa, Dr. F. Marsh, 1013
Teleology, True and False, Dr. C. H. Waddington ; Dr. K. Mather, 705
Telephone : Mine Rescue, R. C. Woods, 235 ; Calls, Long-distance, Automatic Service of, W. Hatton, 944
Telephony, Transcontinental, Twenty-five Years of, 457
Television Projection, Large-Screen, Dr. A. H. Rosenthal, 1028
Temperatures, Lowest, Thermodynamics and the, Dr. C. G. Darwin (Kelvin lecture), 954
Terminal Velocities, Dr. H. Chatley, 64
Terrestrial Magnetism and Electricity, edited by J. A. Fleming ; Prof. S. Chapman (*Review*), 47
Tertiary Siphoneous Algæ in the W. K. Parker Collection, with descriptions of some Eocene Siphoneæ from England, L. and J. Morellet (*Review*), 810
Thames Subway, A New, [1870], 80
Theiler, Sir Arnold, Memorial to, 557
Thermal : Neutrons in Thorium, Lead and Uranium 238, Capture Cross-sections for, Prof. L. Meitner, 422 ; Diffusion in Liquids, Demonstration of, D. Taylor and Dr. M. Ritchie, 670
Thermodynamics : Statistical, a version of Statistical Mechanics for Students of Physics and Chemistry, Prof. R. H. Fowler and Dr. E. A. Guggenheim (*Review*), 239 ; The Structure of Matter, A. R. Ubbelohde, 488 ; and the Lowest Temperatures, Dr. C. G. Darwin (Kelvin lecture), 954
Thiamin, Enzymatic Phosphorylation of, Mechanism of the, M. A. Lipton and Prof. C. A. Elvehjem, 226
Think, How we, and Why, Prof. A. D. Ritchie (*Review*), 798
Thionyl Chlorofluoride, H. S. Booth and F. C. Mericola, 786
Thiophosphoryl, Sulphuryl and, Fluorides, Structures of, D. P. Stevenson and H. Russell, 393
Thorium, Uranium and, Fission of, under Deuteron Bombardment, Dr. R. S. Krishnan and Dr. T. E. Banks, 860
Thought, The Nature of, Prof. B. Blanshard. 2 Vols. (*Review*), 798
Thylacine or Tasmanian 'Wolf', Position of, M. R. S. Sharland, 555
Thyroid Gland and Potassium Metabolism, Prof. I. Abelin, 935
Tibet, Travellers in, late H. Hosten, 710
Tibetan Coronation, 342
Tikopia : of the Solomons, Ritual in, 435 ; The Work of the Gods in, Prof. Raymond Firth. Vol. 1, 435
Timber : its Properties, Pests and Preservation, Dr. F. Y. Henderson (*Review*), 1003
Time : The Nature of, Prof. J. W. Campbell, 426 ; Prof. H. Dingle, 427 ; Relativity of, Dr. F. C. Powell ; Prof. H. Dingle, 626
Tobacco Mildew, Control of, P. J. Anderson, 786
Tomato, Seed Weight in the, L. C. Luckwill, 33
Tompkins, Mr., in Wonderland : or Stories of *c*, *G*, and *h*, Prof. G. Gamow (*Review*), 567
Torpedoes, Early, [1870], 679
Totaquina, M. Ciuca, 458
Town's Refuse as a Source of Soil Organic Matter, Dr. E. H. Tripp, 56
Toxic Gases in Industry, Methods for the Detection of, 100
"Traces", Use of Adsorption Processes for the Detection of, K. L. Sutherland, 553
Transformation Liquid to Solid, Surface Potential Changes of Thin Films in the, Dr. C. Ockrent and W. H. Banks, 861
Transformer Noise, Limitation of, B. G. Churcher and A. J. King, 1029
Transformers, Insulation Stresses in, J. L. Thomas, 468
Transpiration into a Saturated Atmosphere, Prof. H. H. Dixon and J. S. Barlee, 352
Transport in Many Lands, W. R. Foran (*Review*), 295
Trees, Radial Growth of, Weather and, C. J. Lyon, 595
Trench Fever, Dr. R. Schapiro, 547
Trephining, Prehistoric, Technique in, T. W. Parry, 594
Trichoptera, Comparative Morphology and Evolutionary Trends in, P. J. Deoras, 976
Trigonometrical : Survey of England and Wales, [1870], 41 ; Tables : Seven-figure, for Every Second of Time, prepared by H.M. Nautical Almanac Office (*Review*), 482 ; with the Argument in Time (*Review*), 482
Troposphere, Radio Wave Reflections in the, L. G. Stoodley, 743
Trotula and the Ladies of Salerno, Dr. H. P. Bayon, 507
Trout : Habits and Habitats of, W. Rushton (*Review*), 50 ; Streams : Conditions that Determine their Productivity and Suggestions for Stream and Lake Management, Dr. P. R. Needham (*Review*), 50
Trout's Egg, Rhythmical Impedance Changes in the, Lord Rothschild, 744
Truth, The Repudiation of, 871
Tsunamis, B. Gutenberg, 193

Tubellaria from Bermuda and the Sargassum, L. H. Hyman, 750
Tubercle Bacillus, reaction to, Possible relation between ability to Synthesize Vitamin C and, Dr. T. W. B. Osborn and J. H. S. Gear, 974
Tuberculosis : Native Races and, 144 ; and War, Dr. E. Rist, 506 ; and National Health, Dr. H. H. Thomson (*Review*), 660 ; Pulmonary, Urinary Excretion of Combined Ascorbic Acid in, S. Banerjee, P. B. Sen and Prof. B. C. Guha, 706
Tumours : 3 : 4-Benzpyrene, Paramecium and the Production of, J. C. Mottram, 184 ; Metabolism of, Dr. F. Dickens, 512 ; Dr. E. Boyland, 513 ; in Mice, Production of, by Deoxycholic Acid, Prof. J. W. Cook, Prof. E. L. Kennaway and N. M. Kennaway, 627 ; Carbohydrate Metabolism of, I. Berenblum, Dr. E. Chain and N. G. Heatley, 778 ; Dr. F. Dickens and Dr. H. Weil-Malherbe, 779
Tung Oil, Dr. M. Ashby, 738
Turkey : The Earthquake in, E. Tillotson, 13 ; Power Development in, 891
Twilight : Origin of the Yellow Line in, and the Night Sky Luminescence, E. Tönsberg and Prof. L. Vegard, 588 ; the Atmospheric Layer from which the Yellow Line in, Originates, Prof. L. Vegard, 623
Tyndall on Haze and Dust, [1870], 160
Typhoid Fever, Memorandum on, 24

Ultracentrifuge, The, Prof. The Svedberg and K. O. Pedersen and others ; J. St. L. Philpot (*Review*), 566
'Ultra-Perceptive' Faculty, The, Dr. J. Hettinger, 430
Ultra-Violet and Infra-Red Radiations on the Farm, L. C. Porter, 257
Ulu Kelantan, Malaya, New Neolithic Site in, H. D. Noone, 112
Unborn, Biography of the, Margaret Shea Gilbert (*Review*), 814
Underground Traffic and Pedestrian Routes, Lighting of, Prof. R. d'Arboville, 22
Units : New, in Physics and Engineering, Suggestions for, 597 ; Heat, [1870], 599
Universe, The Mass of the, Surgeon Rear-Admiral C. M. Beadnell ; Sir Arthur Eddington, 549
Universities : Treasury Grant to, 299 ; in War-time, The, 319 ; Dr. R. Priestley, 381 ; Research and Invention in, 639 ; The, and Research, Dr. J. I. O. Masson, 855
Uranium : -X_2, Energies of β-Particles from, Dr. D. Roaf, 223 ; Isotopes : Nuclear Fission of Separated, Dr. A. O. Nier, 736 ; Separation of, W. Krasny-Ergen, 742 ; and Thorium, Fission of, under Deuteron Bombardment, Dr. R. S. Krishnan and Dr. T. E. Banks, 860
Urea : Formation of, S. J. Bach, 193 ; Stibamine, Chemistry of, Sir Upendranath Brahmachari, 1021
U.S.A. : Tennessee Valley, Mound Exploration in the, 128 ; Helium Production in the, Dr. C. W. Siebel, 257 ; National Research Council, award of a fellowship in protein chemistry to Dr. I. Fankuchen, 385 ; Suggested Grid, in the, 418 ; New Seismographic Equipment in the, 419 ; New Commercial Fruits in the, O. Atkins ; S. J. Lynch, 458 ; Criminal Anthropology in the, Dr. A. Hrdlička, 738 ; National Museum Report for 1939, 739 ; Maternal Mortality figures for 1938, 740 ; Accidental Deaths in Old Age in, 775 ; Progress of Education in, 776 ; Venereal Disease in, 854 ; Educational Legislation, A Review of, 1937 and 1938, W. Keesecker, 930
U.S.S.R. : Academy of Sciences, Joseph Stalin elected an honorary member of the, 24 ; Biogeography in the, Dr. B. P. Uvarov (*Review*), 52 ; Archæology in the, Prof. V. Gordon Childe, 110 ; the Writer of the Note, 111 ; Finland and the, 456
Uterus : Behaviour of the (*Review*), 762 ; Physiology of the, with Clinical Correlations, Prof. S. R. M. Reynolds (*Review*), 762

Vacuum Flask, History of the, Sir William Bragg, 408 ; Lord Rayleigh, 625 ; G. H. Gabb, 862 ; Lord Rayleigh, 940
Valve Oscillators : Theory and Design of, for Radio and other Frequencies, Dr. H. A. Thomas (*Review*), 501
Vegetable Crops, Prof. H. C. Thompson. Third edition (*Review*), 283
Vegetation of the World (Plant Geography, Vol. 3), A. P. Il'inskij (*Review*), 52
Venereal : Disease : Prevention of, Dr. Marie Carmichael Stopes. Third edition (*Review*), 660 ; in the U.S.A., 854 ; Diseases in War-time, 216
Ventilation : A Handbook on, including Air Conditioning, P. L. Marks (*Review*), 501 ; War-time, A. Peel, 737
Venus, Transits of, in 1874 and 1882, [1870], 474
Vertebrate Egg, The Oldest, Prof. A. S. Romer and Ll. I. Price, 516
Vibration in Engineering Practice (*Review*), 991
Vibrations and Balancing, Mechanics applied to, D. L. Thornton (*Review*), 991
"Victorian Socialism", H. G. Wells ; Dean W. R. Inge, 152
Vienna Institute of the History of Medicine, Prof. F. Lejeune appointed professor, and director of the, 24

NATURE

"To the solid ground
Of nature trusts the Mind that builds for aye."—Wordsworth

Vol. 145 SATURDAY, JANUARY 6, 1940 No. 3662

RECONSTRUCTION IN EUROPE

EVEN in the stress and strain of the war itself, the widespread concern as to the steps to be taken to ensure that our efforts are not once again in vain is unmistakable. Only the creation of a new order founded on truth and justice can compensate for the sacrifices that have to be made, and the creation of such an order involves the co-operation both of belligerents and of neutrals. The extent to which this is evident is one of the most significant differences in the present temper of the nation in contrast with its entry into war in 1914.

While, however, it is well to bear in mind our failure to give effect to our purpose twenty years ago, there are to-day advantages which we did not then possess. The economic distress and confusion into which the life of Europe had been thrown would have endangered any political system. The design of the League of Nations demanded much larger ideas and sympathies than those which guided the treaty makers at Versailles, and surrender to the passions of the hour placed fatal obstacles in the way of the success of the new system. The mistakes and failures of the past are ours to profit by in the attempt to build again on ampler lines.

Nor should we write off the League of Nations as a complete failure. One of the most encouraging features of the last two decades has indeed been the success of its work in certain technical fields such as health, communications and transport, the welfare of women and children. That work remains and continues, as does the work of its sister body, the International Labour Organisation, and their significance will increase.

Many believe that the real weakness of the present League of Nations lies in the retention of national sovereignty. They take the view that no system of collective security can be effective unless it is part of a plan for federal government. Essentially this point of view was foreshadowed by de Madariaga in 1937 in "Theory and Practice in International Relations", and more fully in his later "The World's Design". De Madariaga insists that the nations must discard the habit of thinking of foreign affairs because there are only world affairs, and that behind any machinery, such as the League or a reformed league, for world government, there must be a sufficient body of world citizens endowed with the necessary world patriotism to give world statesmen their inspiration and guidance.

It is on the foundation of a world community that de Madariaga bases his design, the building of world institutions such as a world administration to govern mandated territories, a world bank, a world trade commission and the utilization of existing international institutions, proceeding *pari* *passu* with the promotion of a sense of world citizenship. In the moral basis which he advocates, de Madariaga is arguing on similar lines to Curtius in his brilliant "Civitas Dei", and his contention that, by starting with certain practical problems, the professional interest in getting a problem properly solved may gradually come to eliminate others and substitute the disinterested, rational, exploratory type of mind for the acquisitive, the dogmatic or authoritative, will commend his approach to scientific workers.

Proposals of this type would conserve what is most worth while and possibly gain time for the development of a sufficiently advanced world opinion for acceptance of the idea of some form of federal government or union. This latter idea is outlined in detail in C. V. Streit's "Union Now". The general principle of a federal solution is reasonable in its fundamental premises, and many would be disposed to agree, at least in theory, with proposals to establish a federal government with supreme and single authority to use armed force against aggression by any nation or group outside the Federal Union, to control the use of raw materials in undeveloped territories now subordinate to its members, and to undertake the education of backward communities without racial discrimination.

For some such objectives as these much support could be found. The New Commonwealth, a body which has advocated the creation of an international police force, has been one among numerous factors disposing many to accept the limitations on national sovereignty involved in a federal or commonwealth solution. It is in the means to be taken to achieve a federal union, and the exact extent and nature of such a union that differences of opinion arise, and the practical difficulties are much greater than Mr. Streit is disposed to admit in his facile argument for union now.

Mr. Streit advocates a union of fifteen democracies of the North Atlantic, including a common citizenship, defence force, customs system, currency and postal and communication system. He urges that such a union would be so powerful in its combined resources as to assure peace to its members from the start through overwhelming preponderance and invulnerability. This number is chosen as the most practical nucleus for the organization of world government, and providing geographically, culturally, commercially, financially, politically, and historically, a cohesive nucleus. A start with the democracies is essential, because Mr. Streit proposes to base it on individual citizenship and not on the State itself as unit.

From this start Mr. Streit contemplates the growth of the Union into universal government by peaceful accession to its membership and by co-operation from the start with non-members. Despite, however, the force of Mr. Streit's contention regarding the rich heritage of the democracies in freedom and justice, we may well feel that he is unduly optimistic in arguing from American or Swiss experience as to the rate of progress in achieving such a federal union, and this view is not dispelled by his brusque treatment of the way in which the problems of a common defence force, currency, customs and postal systems are to be solved. Apart altogether from such details, there are other opinions as to the extent of federalism which should be our immediate objective, and the wisdom of scrapping entirely the experience and organization already obtained in international co-operation.

Mr. Streit's plan for union is based essentially on community of ideas and interests. An alternative to this is the Continental basis, essentially as advocated by Briand in his proposal for a European Union, though here also there is some community of ideas. Briand's plan, which lapsed largely through the refusal of Great Britain to link her fate with that of the Continent, has been revived in essence in the European Federation recommended by Count Coudenhove-Kalergi, who visualizes the world as moving towards a large group system. The Pan-American Union being organized by the United States and the Soviet Union are already examples, and a great Mongol block in the Far East is possible in the future. The peoples who care for justice, international law and the rights of men must work for the organization of Europe on good principles and under democratic influences, or that organization will be done by other hands.

A European federation might be easier to secure than the union advocated by Mr. Streit, and involve less risk in attaining it. The attitude of Great Britain will be as decisive a factor in achieving the United States of Europe as the attitude of the United States of America would be in the establishment of the Union of Mr. Streit's plan. What is most important, however, at the moment is not the choice between one plan and another, but the careful and impartial examination of the problems which have to be faced by any system of union, whatever the powers it bestows on the Federal Government.

A main argument for Mr. Streit's plan is that the peoples embraced in his Union are all with long experience of Parliamentary government, and that their economic strength and command of essential materials would be able to assure peace. Count Coudenhove-Kalergi contends that this in itself would be a provocation to the non-democratic powers and would facilitate Germany's dream of creating a federation in Central and Eastern Europe in which she would play the part Prussia played in Bismarck's German federation. His plan would offer Germany and Italy a place in the federated Europe, and while their claims to domination would be resisted, the whole of Europe and a great part of Africa would be their living space.

Unquestionably a Europe organized on a basis of close co-operation between the several States would provide peaceful and constructive opportunities for the varied elements in Germany. Co-operation between such a federation and the Pan-American Union could scarcely fail to secure the peace of the world.

A major difficulty will, of course, be the safeguards to be provided against a repetition of aggression. It is for this reason that we must think of the settlement after the present war not simply in terms of ideals or of military or political force, but as an essentially practical problem—that of utilizing to the maximum the enduring moral and constructive forces which already exist and applying them to the changing conditions as well as supporting them with adequate combinations of force. This factor alone should render us chary of discarding too readily the League of Nations, and should induce us to examine rather more carefully than Mr. Streit has done the causes of its failure or impotency.

Mr. Streit's examination of the League is somewhat warped by preconceived ideas. The League and a federal system are not, as he assumes, necessarily opposed ideas. The League Covenant, for example, lays heavy limitations on national sovereignty, and under it the way is open for gradual and successive further surrenders of national sovereignty until an effective federal scheme is built up. There is at least reason for legitimate doubt whether, if the League has failed because its member States were unwilling to observe its more moderate limitations in their national sovereignty, there is any real prospect at the present time of their entering a federal system which involves an immediate and much more drastic surrender of the essentials of national sovereignty.

Granted that the federal idea probably offers the best ultimate prospect of achieving a lasting peace, the practical question is rather the steps by which we are to advance to that position, more especially when we take into account that the evolution of the British Commonwealth, for example, so far as the Dominions are concerned, is away from any kind of union. In such circumstances, it is imperative to build on any solid foundation that lies to hand.

Reference has already been made to experience and directions in which the work of the League of Nations and of the International Labour Organisation offers hope of further advance or success, and the studies or work on population questions, including migration, and on nutrition are of special promise in this respect. Beyond this we have in being to-day, in the Supreme Council and the Allied High Command, a standing organ of government with a powerful influence over two distinct Sovereign States, and a combination of armed forces under unified control. If these arrangements were kept functioning after the war, a nucleus would be provided on which an international body could be built.

If a way forward to increasingly close combination of European nations is at least possible, the forms of organization which the war is compelling us to adopt for negative purposes could equally be turned to the positive purpose of developing world resources by finding a beneficent outlet for the constructive energies of all peoples. Much progress has been made in establishing successful international commodity schemes, which form instruments of orderly development and are also powerful economic weapons. Steel, tin, zinc, aluminium, rubber, sugar, meat and other vital products are already under some form of international control. The technique of operating such controls is rapidly improving, and consumer interests are being increasingly brought to bear on their operation. This process would be assisted by the creation of an international supervisory body such as a Cartel Commission of the League of Nations, with strong personnel and powers to ensure publicity.

It is difficult to over-estimate the possibilities of such schemes. They have given the world an instrument for the scientific adjustment of expanding production to expanding consumption, thus reducing the chances of further acute world depressions, with their shocks to the stabilizing factors in international relations. The establishment of wind-breaks against economic blizzards of the severity of those of the period of 1929–32 is essential for peaceful and orderly political development.

Moreover, world economic organization appears to be approaching the point when international finance and trade can be greatly assisted by the concerted use of new methods. Internationally organized marketing, supported by international public works, might now be able to give for the first time a peaceful and lasting outlet for the world's energy comparable in scale with that which war supplied in the past. Already, impartial and scientific studies of such problems, often under the ægis of the League of Nations, have provided a basis for cash and price insurance schemes for the world's farmers, measures of conservation for soil, water, fauna and flora, education and health services and modern systems of taxation in backward countries, on a scale impossible even a few years ago. Here may lie a channel the further scientific exploration of which might provide a solution of the problems of colonies and raw materials.

The fact that in many fields the basis for a scientific attack on outstanding problems has already been provided is at least encouraging, and the possibilities of advance are greater than a quarter of a century ago, even if many difficulties remain. That the problems of reconstruction are already being discussed is a further hopeful sign, and evidence that the mistake of postponing until after victory in war the thought and study concerning the needs and structure of a new Europe will not be repeated. Preparation for the tasks of peace cannot be left until they suddenly and urgently arise, to be dealt with in an atmosphere of bitterness, weariness and economic chaos.

There is much to be said for the immediate appointment of a body of able and far-sighted men, chosen irrespective of party attachment, to begin at once the study of this most vital problem. In that study the co-operation of neutral countries should already be possible, and the way should be open for German co-operation immediately the present tyrannical leadership of that country has been replaced.

The contribution of scientific workers will be essential in the investigation of many of the problems of reconstruction which must be solved if we are to build a new Europe. The scientific spirit must be an effective influence if an impartial solution is to be obtained undisturbed by prejudice or vested interests; and scientific workers no less than other members of the community have their part to play in seeing that the problems of peace are approached now in a magnanimous and serious spirit, with the courage, vision and resolution which are essential if a new order in Europe is to pass from a dream into reality.

ISLAM'S CONTRIBUTIONS TO SCIENCE

La science arabe et son rôle dans l'évolution scientifique mondiale
Par Aldo Mieli. Avec quelques additions de Henri-Paul-Joseph Renaud, Max Meyerhof, Julius Ruska. Pp. xix+388. (Leiden: E. J. Brill, Ltd., 1939.) 12.50 guilders.

IT is only within the last half-century that systematic investigations have been made into the part played by Islam in the development of science. Earlier estimates of its importance were mainly conjectural and thus variable, religious prejudice tending to depreciation and the principle *omne ignotum pro magnifico* to exaggeration. One of the first serious attempts to set the inquiry upon a proper basis, by direct reference to original sources, was made by M. P. E. Berthelot, who in 1893 published the Arabic text of certain Muslim alchemical treatises in his "Chimie au Moyen Âge". Other very valuable pioneer work was carried out by E. Wiedemann (on Arabic chemistry and physics), M. Steinschneider (mainly bibliographical), H. Suter (on Muslim mathematicians), E. G. Browne, L. Leclerc and L. Choulant (medicine), and M. J. de Goeje (geography). More recently, Muslim chemistry and mineralogy have been closely studied by J. Ruska, H. E. Stapleton and P. Kraus; medicine (particularly ophthalmology) by M. Meyerhof; mathematics by Salih Zaki of Istanbul; and Muslim philosophic thought in general by Baron Carra de Vaux and De Lacy O'Leary. This list, though representative, includes only a small fraction of the large band of scholars to whom the publication of very numerous Arabic texts—with translations, commentaries, glossaries, notes, and all the other impedimenta of learning—is due. Complementing these labours, and indeed often their condition precedent, are such monumental works of reference as the "Encyclopædia of Islam" (now successfully completed), C. Brockelmann's "Geschichte der arabischen Litteratur", and G. Sarton's "Introduction to the History of Science".

Sufficient data have therefore been amassed to make a general estimate of Muslim science both possible and desirable ; and M. Aldo Mieli has now provided us with it in the work under notice. M. Mieli, as permanent secretary of the International Academy of the History of Sciences, and himself an erudite historian of science, was in a situation peculiarly favourable to the composition of such a work of synthesis. Enjoying the personal friendship of the leading investigators (some of whom, namely Adnan, Brunet, Meyerhof, Renaud and Ruska, read the proofs), and editing *Archeion*—one of the principal journals devoted to the history of science—he could be sure that nothing of first importance escaped him, while errors would almost certainly be detected. But though M. Mieli was thus fortunately placed for his venture, and though he makes generous acknowledgments to his helpers, it is clear that the main credit for an excellent book is his alone. His material is admirably arranged, his style is clear and pleasant, and the book is well annotated, documented and indexed. It may be read without difficulty by those with a merely general interest in the development of science during an obscure period, but provides also a remarkably useful résumé for the specialist. The bibliographies, though not claiming to be exhaustive, include references to the chief authorities, and are supplemented by lists of various important texts still unpublished : an invitation to scholars which will attract new recruits while spurring on the veterans to further efforts.

In the introduction to his book, M. Mieli points out that Arabic science forms the connecting link between the natural philosophy and technology of antiquity and the scientific knowledge of modern times. To exhibit his subject in the proper setting, therefore, he begins with a short but skilful survey of Indian, Egyptian and Greek science. Even in his self-imposed brevity, he finds space for a dig at the philologists who attempt to interpret classical scientific or technical terms without a knowledge of the science or art concerned. He reminds us of the familiar conception of triremes as ships propelled by three *superimposed* banks of rowers, and says that while this conception is impeccable from the philologic point of view, "un pêcheur quelconque de vos côtes aurait pourtant pu rire au nez de monsieur le philologue qui aurait voulu lui affirmer que de tels navires, si même ils avaient été construits, auraient pu naviguer". In point of fact, as was shown by Lefebvre de Noëttes in 1935, the three sets of rowers in a trireme were disposed horizontally, not vertically.

M. Mieli then proceeds to describe the rise and development of Islam, devoting special attention to the tenets of the Ismā'ilite sect, which had so great an influence upon the later character of Muslim scientific philosophy. The celebrated encyclopædia of the Ikhwān al-Safā (Brethren of Purity), for example, is permeated by Ismā'ilite doctrine, while according to Kraus the works ascribed to Jābir ibn Ḥayyān were also products of the same sect. In the body of the book, the author treats his subject partly by period, partly by the particular branches of science, and partly under the names of distinguished individual savants such as Al-Bīrūnī, Al-Rāzī and Maimonides. This method allows considerable flexibility and increases the ease with which the book may be read. In less adept hands, it might have led to a staccato scrappiness, but in fact its results here have been very satisfactory

After dealing with Muslim science at its zenith, M. Mieli describes the process, or rather processes, by which it was transmitted to the West. There were at first sporadic and often somewhat curious infiltrations, as for example when the merchant-turned-doctor Constantine the African emigrated from Carthage to Salerno, became a Christian, and inoculated the Salernitan School with a passion for Muslim medicine (eleventh century). More ample contacts between Islam and Latin Christianity were made in Sicily, in Moorish Spain, and through the medium of the Crusades. Countless translations were made, and countless European students sat at the feet of Muslim teachers, so that in a surprisingly short space of time the Arabic version of Greek science, together with the large contributions to knowledge made by the Muslims themselves, became immediately and universally available. By a strange coincidence, the transmission once made, Muslim civilization and science alike evolved rapidly to an irremediable decadence.

The remaining portions of the book deal with bibliographies, with certain Arabic scientists and writers posterior to the thirteenth century, and with the constitution and aims of the International Academy of the History of Sciences. The index of names is divided into three parts : (1) persons who lived before the Hegira, (2) persons living between the Hegira and the end of the twelfth century, and (3) persons living in the Christian West, since the fourteenth century. The last part includes the names of modern authorities.

E. J. HOLMYARD.

A DEFENCE OF VITALISM

Vitalism: Its History and Validity
By Dr. L. Richmond Wheeler. Pp. xii + 276. (London: H. F. and G. Witherby, Ltd., 1939.) 15*s.* net.

MANY readers of Radl's "History of Biological Theories" and Woodger's "Biological Principles" must have been left with the feeling that biological theories are quite incoherent and biological principles non-existent. Dr. Wheeler has set himself to correct the impression left by such excessively impartial discussions. His book is a history of vitalistic theories and a defence of this point of view. It is a praiseworthy but incomplete attempt to do something extremely difficult. To complete the task satisfactorily would mean a complete history and criticism of the development of scientific thought and its varying background. As vitalism has been an attempt to supplement or set aside the traditional categories of physical science, these have to be examined first. The task is not made easier by the way that vitalists and mechanists in their age-long contest have repeatedly shifted their ground and changed their weapons. If there is a clear and permanent difference between the antagonists, it may be one of temperament as much as anything else. The mechanist is the kind of person who feels that everything important is known already, in principle at least, and that only minor details remain to be discovered. The vitalist feels that existing knowledge is only of minor details, and everything of importance is undiscovered.

The author's brief treatment of the seventeenth and eighteenth centuries is scarcely adequate for the period when the foundations of modern scientific and philosophical thought were being laid. In those days, too, the division of opinion was better defined. The vitalists really believed in 'vital forces'. The mechanists really believed in the all-sufficiency of Newtonian mechanics. In fact, Hobbes believed it when the science of mechanics was scarcely more than a hope and an aspiration. In the nineteenth century the controversy became more confused. The mechanists could not rely on mechanics only but had to add chemistry to their list, regardless of the fact that chemistry was an autonomous science owing very little to physical theory and called mechanical only by courtesy. The vitalists on the other side began to fight shy of vital forces and call them by other names.

In the present century the wholesale reconstruction of physical theory has made further complications. Dr. Wheeler says (p. 172): "Vitalism and mechanism are the only two types of theoretical biology yet devised and both involve the analogy of a humanly constructed machine. Vitalism allows for a mechanic. Mechanism forgets that a mechanic is essential . . ." This is true enough of the traditional controversy and is still true of some of the controversialists, but not of all. If it is true, does it not condemn both sides? The analogy of a humanly constructed machine is, to put it mildly, a dangerous one and may be entirely wrong. There have not been lacking thinkers who pointed this out and for various reasons refused to take either side. Dr. Wheeler is scarcely fair to these 'cross-benchers', and tries to count them in on his side. For example, he scarcely considers the positivists at all. Mach is just mentioned in passing as an anti-mechanist. It is true that positivists deny any absolute truth to mechanical theories, but they are admitted to a secondary sort of truth as "conceptual shorthand" or "convenient fictions" if they help to predict observable facts. But vitalist theories would be utterly condemned as metaphysical and of no heuristic value. Positivism, however seriously mistaken, is an interesting and influential type of theory that should not be ignored. J. S. Haldane, too, is treated as a vitalist, though he always said he was not. His contention was not quite the usual one, that biology is an autonomous science with its own concepts and methods distinct from those of physics, but that the special concepts of biology are really prior to those traditionally used in physics and are really applicable to physics. If physicists have not used them, so much the worse for physics.

Dr. Wheeler sums up his discussion with a list of fourteen arguments in favour of vitalism—all those used by Driesch and several others. What is unsatisfactory about them is that they are all negative. They are designed to show that mechanism is not able to solve all problems and provide an all-sufficient philosophy. The mechanist might reply that he never said it did; he only claims that it suffices to supply all the useful information that has been or is likely to be obtained. There is no answer to this retort unless the vitalist can point to something positive on his side. Driesch's attempt was not a success because he hesitated between the old 'vital force' theory and the view that living organisms have minds, though perhaps very little ones. Neither view is necessarily absurd, nor if carefully interpreted need it contradict established facts or physical principles; but it is of no value unless it is consistently maintained, and applied in detail to specific cases.

The vitalist's demand for biology to use its own special methods and concepts can be readily granted, provided he can tell us what they are. A purely physical science like meteorology does this very thing. To-morrow's weather might be predicted by calculation using the general laws of thermodynamics and the kinetic theory of gases; but actually it is done by using purely *ad hoc* meteorological concepts and methods. If these concepts can be shown to be derived from the general theory of physics, so much the better; but if not, that is not a fatal defect. Similarly, if one wants to know the density of lead, the viscosity of glycerin or the structural formula of cane sugar, one does not find the values by calculation from the theory of atomic structure. Even if this were possible, it would take too long and give very inaccurate results. It may be suspected that results would only be forthcoming at all when the answer was known beforehand. The function of the general theory is merely to show that what has been accurately determined empirically is roughly the kind of thing that might be expected. In biology every investigator uses *ad hoc* concepts and methods while he is investigating, but as the concepts are difficult to define he may forget about them when he is arguing. For this reason, the Gestalt school of psychologists have done very valuable work in producing special concepts that are sufficiently well defined, can be applied to specific cases, and act as guides to experimental investigation. If as Kohler maintains, Gestalt principles are equally applicable to physics, that is a point in favour of Haldane's view. Dr. Wheeler probably agrees to all this, but he is not very explicit about it.

A USE FOR EVERY CHEMICAL

Uses and Applications of Chemicals and Related Materials

A Guide to the Current Industrial Uses, Potential Applications and Sales Possibilities of 5167 Products. Compiled and edited by Thomas C. Gregory. Pp. vi+665. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1939.) 60*s*. net.

THIS is a book for which many of us have been waiting. Whilst to the more academic among chemists individual chemical substances are mainly of interest on account of their properties, the elucidation of the finer points in their structure or for use in chemical reactions, there is also a large corps of chemists who, aided by engineers, technicians, physiologists and others, are engaged in finding a useful application of as many of them as possible to the better service of humanity.

The last decade has been outstanding in regard to the discovery that all sorts of what may be described as laboratory curiosities can be made to serve useful ends. Practical work of this nature requires a peculiar aptitude which is more common in the United States than in Britain. There also the willingness of the manufacturer to try something new, because it is new, encourages such developments. The point has often been emphasized in the columns of NATURE; perhaps its reiteration at a time when war emergencies are promoting invention will serve a useful purpose.

As the sub-title indicates, the book lists in alphabetical sequence a large number of substances which can be classed as chemicals, including a high proportion of synthetic organic materials. Against each substance is listed its uses, set out under industries again arranged in alphabetical order.

For some substances the uses are already numerous; with others they are limited. It becomes possible very quickly to see whether a use has been found for a particular substance and for what kind of purpose. Thus, turning over the pages at random, ethyltriphosphonium bromide may be used as an agent for moth-proofing furs, feathers and the like as well as textiles.

Montan wax has twenty-seven uses in such diverse industries as electrical, food, ink, leather, metallurgy, paint, paper, perfumery, rubber, textile, etc., all of which are set out succinctly.

Again, orthodichlorobenzene has been applied in freeing hydrochloric acid from arsenic, as an intermediate in making dyestuffs, as a cleansing and polishing agent for brass and as a solvent in all four very varied purposes.

The collection of the material was begun in 1922 by the late Ismar Ginsburg and was continued and expanded since 1933 by Thomas C. Gregory. Most of the data have been published in the *Oil, Paint and Drug Reporter* regularly since 1922, where supplementary surveys covering additional products and new uses will continue to appear.

The practical value of the book need not be further stressed; the only criticism from the point of view of the British reader is the high cost, which will restrict its circulation here.

MATHEMATICAL METHODS IN ECONOMICS

Économie théorique et statistique économique (1) Théorie mathématique de la valeur en régime de libre concurrence. Par J. R. Hicks. Pp. 56. 18 francs. (2) Les fondements mathématiques de la stabilisation du mouvement des affaires. Par Prof. J. Tinbergen. Pp. 114. 30 francs. (Actualités scientifiques et industrielles, 580 et 632.) (Paris : Hermann et Cie, 1937–38.)

IN the classical economics of Marshall, it was assumed that a consumer spends his income so as to obtain the maximum possible 'utility', and it was deduced that the prices of commodities must be proportional to their marginal utilities. The weak point of this is that no one knows exactly what this utility is, and still less how it can be measured. Modern mathematical economists, in particular E. Slutsky, J. R. Hicks, R. G. D. Allen, have, by developing Edgeworth's 'indifference curve' and Pareto's 'scale of preference', succeeded in constructing a theory of value on a new and much sounder basis. All that is assumed is that the consumer knows, of the various sets of goods purchasable for a given sum, which he likes best, which second best, and so on. It is amazing how this apparently inadequate postulate is adapted to mathematical treatment, including the use of the differential calculus to determine the maximum satisfaction obtainable with a limited amount to spend.

Consider any set of numbers the order of magnitude of which indicates a consumer's order of preference without any pretence of measuring its magnitude. These form a function of u. The most general 'index of preference' is an arbitrary function of u. The marginal utility is also arbitrary, but the ratio of two marginal utilities has a definite value, as the arbitrary factor cancels out. This ratio is called the marginal rate of substitution, and is fundamental in the new theory. All the old work involving marginal utility can be employed, provided that the conclusions do not involve the arbitrary function.

One of the most important results is Slutsky's 'fundamental equation of the theory of value', which can be interpreted in terms of Marshall's elasticities. Further developments include the general equilibrium of exchange and of production ; but it is not necessary to describe these in detail, as the novelty of the work lies in its premises rather than in its conclusions. Prof. Hicks's tract is written for those with considerable mathematical attainments ; a comparatively non-mathematical account, with extensions to a much wider field, will be found in his "Value and Capital".

We now come to a more difficult branch of mathematical economics, dealing with the case when there is a time-lag between cause and effect. As a first approximation, Prof. Tinbergen makes a number of simplifying assumptions, such as that sales, profits and investments depend, not on the actual prices, wages and interest, but only on their mean values. Thus, in this 'macrodynamic approximation', production and prices are treated as a whole ; the variables are really index-numbers. Moreover, certain phenomena which are considered of minor importance, such as the excess of imports over exports, are entirely ignored. He now sets up a large number of equations, based partly on general economic ideas and partly on a careful statistical analysis of conditions in the United States (1919–1932). For example, one equation asserts that the mean price is proportional to the mean amount of sales nine months before, another that the rate of bank interest depends on the balance six months before.

In their general forms these equations are difficult to handle, but if we consider only variations from an equilibrium level, we get, with further approximation, a system of linear finite difference equations with constant coefficients, which are easy to solve. The solutions may be used for two purposes. First, they show how the conditions at a given period can be calculated from a knowledge of those at an earlier period. This is tested by a series of graphs, and the agreement between the calculated and observed results is much closer than might have been expected, in view of the extensive approximations made in the course of the work. Secondly, they show how the general nature of the solution depends on the values of the coefficients, and so how the magnitude of economic fluctuations can be diminished by Government action. Specific recommendations are drawn up for the consideration of the United States Government.

Lack of space compels us to pass over many extensions and applications of the author's method, such as the effect of external perturbations, of speculation, and of fixing salaries or prices. He gives a great deal of matter the importance of which may not be generally realized until it is available in a more extended form. But what seems most valuable is not so much any detail of the work as the general spirit. Physics and other sciences have made great progress because of the constant interaction between observation and theory, and it is likely that this method will prove equally fruitful in economics.

H. T. H. PIAGGIO.

SCIENTIFIC CENTENARIES IN 1940

BY ENG.-CAPT. EDGAR C. SMITH, O.B.E., R.N.

IN looking back once again for the names of men who were born or who died, one, two, three or more centuries ago, to whom the world is indebted for some discovery, or contribution of note to the progress of modern science, the first name which stands out clearly is that of William Gilbert, the physician of Elizabethan days. He was born in 1540. When sixty years of age he published his famous book "De Magnete, magnetisque corporibus et de magno magnete tellure". This was the first great work on physical science published in England. A century or so after Gilbert died, Dryden wrote the lines

"Gilbert shall live till loadstones cease to draw
Or British fleets the boundless ocean awe."

Gilbert was born at Colchester towards the end of the reign of Henry VIII. At the age of twenty he graduated from St. John's College, Cambridge. He afterwards spent some years in travel and study on the Continent and in 1569 obtained the degree of M.D. Four years later he settled in practice in London and ultimately became physician to Queen Elizabeth. His home was in St. Peter's Hill, and one of his haunts was the College of Physicians, then housed in Linacre's house in Knight-Rider Street not far from St. Paul's. He rose to be president of the College; and to it he bequeathed his books, globes and apparatus, but these were all destroyed in the Great Fire of 1666. He died at Colchester on November 30, 1603, and was buried in Holy Trinity Church, in which a monument was erected by his brothers.

Gilbert's experiments in magnetism and electricity mark an epoch in science in Great Britain. They were fully appreciated by some of his contemporaries and Galileo, in one of his "Dialogues", makes the imaginary Salviati say of the "De Magnete": "I highly praise, admire and envy this author for having formed such a stupendous conception on a matter which has been treated by many sublime intellects, but solved by none. . . . I do not doubt that in due course of time this new science will be perfected by new observations and by true and cogent demonstrations. But the glory of the first inventor will not be diminished thereby. . . ."

Another celebrated man of science who was born in 1540, and who died in 1603, was the French algebraist François Viète, commonly known as Vieta. Born at Fontenay-le-Comte, Vendée, he was educated for the law and for some time practised at the bar in Paris. When forty years of age he was given the post of master of requests, attached to the Parliament of Paris, and from that time he gave up his leisure to mathematics. Of the three books printed during his lifetime—for private circulation—the first was his "In Artem Analyticam Isagoge" (1591); this is the earliest work on symbolic algebra. In his article on Vieta, in the old "Penny Encyclopædia", the mathematician Augustus de Morgan wrote: "If a Persian or Hindu, instructed in the modern European algebra, were to ask 'Who of all the individual men made the step which most distinctly marks the separation of the science which you now return to us from that which we delivered to you by the hands of Mahommed ben Musa?' the answer must be Vieta."

Among the French mathematicians born a century after Vieta were Jacques Ozanam (1640–1717) and Phillippe de Lahire (1640–1718). The former wrote nearly twenty books, but he is remembered to-day for his four volumes of "Recreations Mathematiques et Physiques". The youngest son in a well-to-do family, Ozanam was intended for the Church. This prospect, however, had no appeal for him, and he became a teacher of mathematics at Lyons. He there appears to have developed a passion for gaming, but some time afterwards he removed to Paris and devoted himself entirely to mathematics and was elected to the Royal Academy of Sciences. It is said that when religious matters were being discussed he remarked "that it was the business of the doctors of the Sorbonne to dispute, of the Pope to decide, and of a mathematician to go to heaven on a straight line". His contemporary Lahire was the son of a court painter and it was hoped he would become one, but geometry proved too strong an attraction. In his thirties he began observing at the newly erected Paris Observatory where Cassini was similarly employed. By the Minister Colbert he was appointed to assist Picard in geodetical work for the chart of France. He wrote a variety of works and from 1690 onwards held a professorship in the famous Collège de France.

The year 1640 also saw the birth of Dr. Robert Plot (1640–96), author of natural histories of Oxfordshire and Staffordshire, a secretary of the Royal Society and the editor of vols. 143–166 of the *Philosophical Transactions*. When Elias Ashmole established the first University chemical laboratory at Oxford, it was placed under Plot's charge.

The bicentenaries which occur this year recall, among others, the names of two authors concerned with those indispensable works—encyclopædias. In May 1740 Ephraim Chambers died and was buried in the cloisters of Westminster Abbey. As a youth he had come to London from Westmorland to learn globe-making at the hands of Senex. From globe-making he turned to writing and, conceiving the plan for a dictionary of science, took chambers in Gray's Inn and there in 1728 produced his "Cyclopaedia, or . . . Dictionary of Arts and Sciences". It immediately won a reputation for him and he was elected F.R.S. Several editions of his work appeared and it formed the basis of the Cyclopædia of Dr. Abraham Rees (1745–1823). In between the publication of the encyclopædias of Chambers and Rees came that of the "Encyclopædia Britannica" (1771), projected, printed and published by the public-spirited Edinburgh printer and naturalist William Smellie, who was born the year Chambers died.

The record of scientists, inventors and pioneers born in 1740 includes the names of Henry Cort (1740–1800), whose patents of January 17, 1783, and February 13, 1784, for the production of wrought iron plates, bars and rods form a milestone in the history of our iron industry; of Joseph Michel Montgolfier (1740–1810), who with his brother Jacques Etienne Montgolfier (1745–99) made the pioneering experiments with balloons; of the astronomers Thomas Bugge (1740–1815) of Copenhagen, Jacques Andre Mallet (1740–90) of Geneva, Andre Jean Lexell (1740–84) of Sweden and St. Petersburg, and of the famous geologist, physicist and mountaineer, Horace Bénédict de Saussure (1740–99). Like Mallet, de Saussure long held a chair in the University of Geneva, but it was his travels, his observations of rocks and his climbing expeditions which contributed most to his renown. His excursions culminated during the years 1787–89 with the ascent of Mont Blanc, a stay for thirteen days on the Col du Géant, and a tour of Monte Rosa. Mont Blanc, it may be added, was first climbed in 1786 by the hunter Jacques Balmat and Dr. Paccard.

Some of the eminent men of science who died in 1840 were referred to at the anniversary meeting of the Royal Society of that year. Among these was the French mathematician Simeon Denis Poisson (1781–1840); the German anatomist and naturalist Johann Friedrich Blumenbach (1752–1840) and the German astronomer Heinrich Wilhelm Matthäus Olbers (1758–1840). Olbers and Blumenbach when they died had passed the allotted span of life, but Poisson, apparently by his unceasing labour and his neglect of exercise and healthy recreation, had shortened his life. From a boy upwards he had been a prodigious worker. He was a younger contemporary of Lagrange, Laplace, Fourier, Monge, Prony and other members of the brilliant group of scientists in Paris during Napoleonic and post-Revolutionary times. He occupied positions at the École Polytechnique, the Collège de France, and the Bureau des Longitudes. "If he was inferior to Fourier or to Fresnel," said an obituary in the *Athenæum*, "in the largeness and pregnancy of his philosophical views, he was incomparably superior to them in mathematical power: if some of his contemporaries rivalled or surpassed him in particular departments of his own favourite studies, he has left no one to equal him, either in France or in Europe at large, in the extent, variety, and intrinsic value of his labours".

Five others who died in 1840 were Joseph Johann von Littrow (1781–1840), the Bohemian astronomer who from 1821 was director of the Vienna Observatory; André Jean Francois Marie Brochant de Villiers (1772–1840), who with Elie de Beaumont and Dufrenoy made a geological map of France; Nicolas Aylmer Vigors (1787–1840), the Irish M.P. who was a founder and the first secretary of the Zoological Society; Sir Anthony Carlisle (1768–1840), the surgeon who with William Nicholson on May 2, 1800, decomposed water with the aid of the first voltaic pile made in England, and Sir Robert Seppings (1768–1840), an eminent naval constructor in the days of our 'wooden walls'.

Seppings was a shipwright apprentice in 1782, master-shipwright at Plymouth in 1800, and at Chatham in 1804, and in 1813 was appointed surveyor to the Navy, a post he held until 1832. He introduced a form of keel blocks for dry docks which enabled ships to be dealt with rapidly, and a system of diagonal trussing for ships which was extensively used. In 1818 he was awarded the Copley Medal of the Royal Society for his communications on warship construction. He died at Taunton on April 25, 1840, and his monument is in St. Mary's Church.

Of men of science born a century ago in Germany one of the most notable was Ernst Abbe (1840–1905) whose optical investigations, combined with the work of the instrument-maker Carl Zeiss (1816–88) and the glass-maker Otto Schott, made "Jena glass" famous the world over and Zeiss instruments the standard of excellence. Abbe was a professor in the University of Jena at the age of twenty-six he became associated with Zeiss. After Zeiss's death he was responsible for the business, which he formed into a sort of trust called the Carl Zeiss Stiftung. Speaking at the Optical Convention of 1905, shortly after Abbe's death, Glazebrook said that "Abbe's work in Jena is perhaps the most striking illustration of the way in which progress depends on the co-operation of science and experience". Another German physicist born in 1840 was Friedrich Kohlrausch (1840–1910), the successor of Helmholtz and the predecessor of Warburg, as president of the Reichsanstalt at Charlottenburg. In France 1840 saw the birth of Emile Duclaux (1840–1904), an early assistant to Pasteur, who after his master's death became director of the Pasteur Institute.

Sweden has long been famous for its chemists and metallurgists, and among the former are Lars Fredrik Nilson (1840–99) and Per Theodor Cleve (1840–1905). Both studied at Uppsala, both held chairs there and at Stockholm and both were elected foreign members of the Chemical Society. The memorial lecture to the Society on Nilson was given by Prof. Otto Pettersson and that on Cleve by Sir Edward Thorpe. Speaking of the position Sweden occupied in relation to chemistry, Thorpe said that "when regard is had to her position among continental nations—to her chequered political history, to her geographical isolation, the comparative sparseness of her population, her relative poverty, the fewness of her seats of learning—the influence which Sweden has been able to exert on the development of that branch of science, which it is the proper function of this Society to foster, must always excite our wonder, admiration and gratitude. The mere mention of the names of Bergmann, Scheele, Berzelius, Mosander, Gadolin, Nilson, is sufficient to remind us how great have been her services to the science of chemistry".

To this necessarily incomplete list of men distinguished in science, invention or engineering may be added the names of the American geologist Edward Drinker Cope (1840–97); the American-British inventor and engineer Sir Hiram Stevens Maxim (1840–1916); the Irish astronomers Lord Rosse (1840–1908) and Sir Robert Stawell Ball (1840–1913); the Scottish inventor John Boyd Dunlop (1840–1921) of pneumatic tyre fame; the English metallurgist James Riley (1840–1910), and the great civil engineer Sir Benjamin Baker (1840-1907), whose name will always be remembered in connexion with the Forth Bridge, the Aswan Dam and other important constructions. Baker was elected F.R.S. in 1890, and served as president of the Institution of Civil Engineers in 1895. He died at Pangbourne on May 19, 1907, and was buried at Idbury, in the Cotswolds. On December 3, 1909, a memorial window to him was unveiled in the north aisle of the nave of Westminster Abbey.

FOOD FROM GARDENS AND ALLOTMENTS

BY SIR JOHN RUSSELL, F.R.S.,
ROTHAMSTED EXPERIMENTAL STATION

THANKS to numerous official inquiries, the quantities of food required by the population of Great Britain are fairly well known. Our diet is both generous and varied. The total food consumption averages rather more than 900 lb. a head without counting milk and eggs. Apart from these the *per capita* consumption falls into five groups: about 200 lb. each of (1) wheat, (2) potatoes, (3) other vegetables and fruits, and (4) meat and fish combined; (5) some 140 lb. of other foods, chiefly sugar (94 lb.) with smaller quantities of butter (25 lb.), margarine (8 lb.) and cheese (10 lb.).

We produce at home all the potatoes, the liquid milk, and much of the vegetables; about half the meat and fish, but only 15 per cent of the wheat and some 10 per cent of butter. We produce rather less than 40 per cent of the total money value of our foods, and rather less than 50 per cent of the total weight. On an average, for each individual there is in peace time an import of about 4 cwt. of food per annum.

One of the most urgent problems at the present time is to reduce this figure. It is made up roughly as follows:

Wheat	1½	cwt.
Meat and fish	1	"
Fruit, butter, cheese, etc. ..	1	"
Sugar	60	lb.
Total	4	cwt. approximately

The largest item is wheat, of which 170 lb. is imported out of the 200 lb. consumed. We shall, however, produce more. The plan of the Ministry of Agriculture is to plough up two million acres of land in all; in the War of 1914–1918, when this was nearly accomplished, we had added 50 per cent to our wheat production.

If we succeed in doing as much this time, we shall reduce the 170 lb. of imports to 155 lb., but it seems scarcely likely that we can get much below this. Something could be saved by closer milling, but that would only mean less food for our animals and therefore less meat and milk. For one thing we have insufficient land available:

wheat is one of the least economical of all crops to grow so far as land is concerned, for while 1 acre of wheat suffices only for 6–7 persons per annum, 1 acre of potatoes suffices for 70–75.

For meat and fish our imports are about 110 lb. annually out of a total consumption of practically 4 lb. per week per head. Consumption could be cut down by rationing; but in view of the circumstances that our animal population is now larger than it has ever been before, it seems improbable that there will be much shortage during the first year of the War. Even our animals, however, have been living on imported food, though not to the same extent as ourselves; Dr. Wright recently estimated that some 25 per cent of their total food is imported.

The area of land being limited, all increased allocation of land for human food means a reduced area for the growth of food for animals. During the War of 1914–1918 the annual production of milk fell by 400 million gallons, a reduction of 20 per cent, while that of meat fell by 170,000 tons, a reduction of 17 per cent. There were various contributory causes and we shall hope in this War that the fall will not be so great. In seeking to increase production of human food we must not, however, forget our animals.

The import of fruit will be difficult to replace. The Englishman's favourite fruits are bananas, oranges and apples, and two of these must be wholly imported while of the third we produce only a fraction of our total consumption.

Another big item in the import bill is sugar; the 60 lb. of import can be cut down by rationing; we can produce more at home than we are doing and we shall, it is hoped, also make better use of bees. From a reasonably well-kept hive one should obtain some 40 lb. of honey, though this is not a net gain because it involves the feeding of some 10–20 lb. of sugar to the bees. On dairy produce we cannot hope to save much. If there were no waste the ration of ¼ lb. of butter per week would give us 13 lb. a year, not far short of the 16 lb. which was our average until recently.

The most hopeful direction of saving shipping is therefore to economize on meat, fruit and sugar, at the same time increasing our home production of wheat and also of animal food so as to avoid the necessity for reducing home production of milk and of meat.

The question to be decided then is: What part can gardens and allotments play in this programme of production?

Experience in the War of 1914–18 shows that production of potatoes can be readily expanded and with great advantage in every way. The production rose in the last war from 7·5 million to 9·4 million tons—an increase of nearly 25 per cent. Potatoes are not only valuable as food for men and for animals; they are also an important source of starch for various other purposes. They are easy to grow and responsive to treatment.

Vegetables will become of increasing importance as the meat ration is cut down; but unfortunately, while the English gardener can produce them at least as well as anyone else, the English cook usually treats them deplorably. The great difficulty about reducing our meat ration will be that we may be presented with a succession of vegetarian dishes, made dull and tasteless, not through any fault of the vegetables, but because of the incompetence of the cook. For this reason it is very important in any garden or allotment that there should be as wide a variety as possible of vegetables, including particularly those used for salads, and those that can be made up into tasty dishes. Food value is probably of less importance than tastiness; it seems improbable that our dietary would ever be so seriously curtailed as to be lacking in actual food value; the present danger is that it may lack variety and no longer be appetizing. This the gardener should seek to remedy.

It seems inevitable that sooner or later we must face a reduction in the amount of fruit that we usually import; we can scarcely hope to continue our present supplies of oranges and bananas and imported apples. In many gardens there are fruit trees and bushes in a more or less neglected condition. If these were overhauled they might be made to yield better during the coming season; the produce may be very welcome, for the deficiency of fruit must somehow be made good both by growing more at home and by using more vegetables.

The increased garden production of potatoes and vegetables would have several important advantages quite apart from ensuring supplies for the grower's table. Farm land now used for the production of potatoes and vegetables could be released for other purposes, especially for the production of fodder crops for animals, thus saving the necessity for uneconomic slaughter and ensuring continued milk and meat production.

Much internal transport could also be saved. At the present time many parts of Great Britain are not self-supporting in potatoes and vegetables, and considerable quantities have to be transported from county to county, occupying valuable truck space or using up petrol on the roads. It would be a great advantage if this internal transport could be cut down.

The possibilities of increase are considerable. It is estimated that there are some 3½ million gardens and 900,000 allotments in the country. The Ministry of Agriculture is stimulating the formation of new allotments, aiming at establishing another 500,000. Many of the existing gardens and allotments are not, however, fully used, and it is desirable to improve them as speedily as possible. Technical advice is now available in every county. There is, however, a real danger of considerable waste of seed and manure, neither of which can well be spared now. Here there seems a useful opening for local distribution that could ensure distribution of manure and interchange of seedlings so as to avoid the present wasteful methods. Distribution of excess produce is another important problem, for however well the garden is planned it is impossible to avoid an excess at one period and a deficiency at another. Unfortunately, organization of garden production is peculiarly difficult and in the past has rarely succeeded, but that is no reason why it should not again be attempted, as in the last war. Finally comes the important question of utilization of garden wastes; the best way, the keeping of pigs and poultry, is not usually possible. In any event, even if these are kept, the compost heap is an essential part of a good gardener's equipment.

THE EARTHQUAKE IN TURKEY

By E. Tillotson

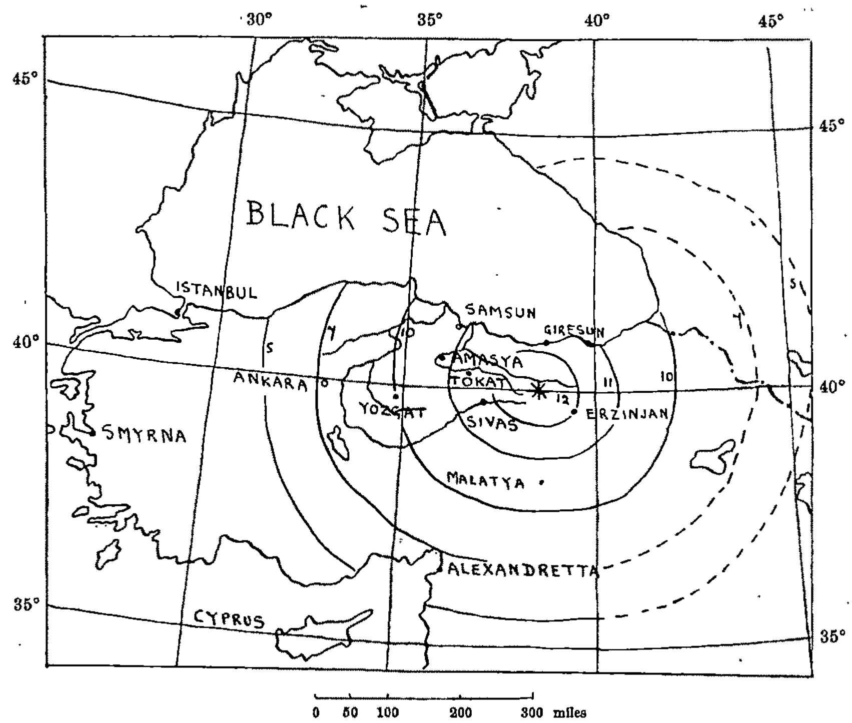
THE greatest earthquake ever recorded in Turkey, and probably the greatest natural catastrophe which Turkey has ever suffered, occurred on December 27, when, between approximately 1.57 a.m. and 5 a.m. local time (East European), there were at least seven terrific earthquake shocks. These shocks caused havoc on and near the Black Sea coast of Anatolia in north-eastern Turkey, where, to the accompaniment of underground rumbling, upwards of fifteen towns having populations of between fifteen and forty thousand persons each, together with more than ninety villages, were practically razed to the ground, communications by telegraph, road and rail destroyed, and estimated casualties of 45,000 killed and 20,000 wounded caused.

The first news of the catastrophe was received from the Bendandi Observatory at Faenza, which reported that an earthquake of catastrophic dimensions was registered on its seismographs at 1 a.m. (Mid-European time). The earthquake was estimated to have taken place in Armenia, and the vibration at Faenza was so intense that the recording instruments were damaged. Similar news came from the Swiss observatories, and at Zurich the shock was received at 1.2 a.m. (Mid-European time). The seismograph belonging to Mr. J. J. Shaw at West Bromwich was also damaged by the earthquake, though Mr. Shaw was away from home at the time. Shortly after the news from Faenza, messages were received from Ankara stating that earthquake shocks had been experienced there.

The full force of the principal shock was felt at Erzinjan, a town situated at an altitude of 4000 ft. above sea-level where a brisk trade was conducted in silks, cotton and copper. The town was immediately reduced to a heap of ruins and about 80 per cent of the population killed. The upsetting of oil lamps and stoves and the breaking of gas pipes caused hundreds of fires to break out in all parts of the town, which the surviving brigades could not extinguish on account of broken pipe lines and huge cracks in the roads. Telephone and telegraph communications were also disrupted. Here, included in the wreckage, were the military barracks and club and military school, where ten officers and ninety cadets are known to have lost their lives, though a much greater military death roll is feared. Damage only a little less severe was done at many other towns. Sivas, a town of 65,000 inhabitants, the centre of caravan routes and a collecting place for the agricultural produce grown in the surrounding districts, together with Tokat in Sivas Province, a town of 31,000 inhabitants engaged largely in calico manufacture, and the intervening villages, were practically wholly destroyed. Many people, in bed at the time of the first shock, were buried alive in the wreckage of their homes. The district of Kemah, the town of Yozgat and the town of Amasya, with a population of 30,000, in the midst of fruit-growing country, are all in ruins. At Samsun in the Trebizond district, a seaport with a population of 15,000, exporting copper, timber, tobacco, wool and other agricultural products, mosques, minarets, schools and public buildings—some of them built of reinforced concrete—and private houses came crashing down, killing thousands of people. Ordu, in the tobacco-growing district, suffered similarly, as did also Giresun, Malatya, Turhal, Gumushane, Refahive and Plumer. On the night of December 28 fires were still blazing amidst the ruined buildings, and to add to the difficulties of the rescue parties a blizzard was raging in the countryside at a temperature of 2° F. Of the 350 inhabitants of the village of Tomruk, only three survivors have been traced. The single-storied mud houses of the peasants suffered terribly.

The first relief train on the recently opened Sivas-Erzerum railway was held up just outside Sivas because of wreckage on the line, twisted rails and huge ground fissures. Most of the geological faults already known in the area have moved, causing large crevices and permanent lateral movement. One of the principal faults along which movement has taken place has been estimated by the director of the Istanbul Observatory to be sixteen miles deep, and many new faults have been formed.

On the basis of the macroseismic data, the accompanying sketch map showing the isoseismal lines has been constructed. The scale used is the modified Mercalli scale of 1931 originated by H. O. Wood and F. Neumann for the Carnegie Institution of Washington and the United States Coast and Geodetic Survey. This scale is numbered 1–12 in ascending order of earthquake intensity, 1 being a shock not felt except by a very few under especially favourable conditions, and 12 being a shock where the damage is total, waves being seen on ground surfaces, lines of sight and level distorted and objects thrown upward into the air. It is extremely rare for a shock to have intensity 12, though many of the great earthquakes described by Davison, and the Chilean earthquake of January 24, 1939 (NATURE, February 11, 1939, p. 230), probably exceeded scale 11, which indicates that few if any masonry structures remain standing, broad fissures exist in the ground, underground pipe lines completely out of service, and rails bent greatly. Scale 7 indicates that damage has been negligible in buildings of good design and construction but considerable in poorly built or badly designed structures, whilst scale 5 shocks are felt by nearly everyone, break some dishes, crack some plaster and overturn unstable objects. It should be noticed that such intensities are influenced by ground conditions as well as by the energy causing the displacements, and, since buildings once cracked may succumb to prolonged shaking, the total period of shaking would appear to be an important factor.



SKETCH MAP SHOWING THE APPROXIMATE EPICENTRE AND ISOSEISMAL LINES (MODIFIED MERCALLI SCALE OF 1931) OF THE ERZINJAN EARTHQUAKE OF DECEMBER 27, 1939.

*, EPICENTRE ; —10—, ISOSEISMAL LINE.

The greatest of the shocks was certainly world-shaking so far as modern seismographs are concerned, since these are capable of registering measurable ground displacements of less than 5 μ (where $\mu = 0{\cdot}001$ mm.). It was registered at observatories throughout the British Isles and in the world in general. The fact that seismographs as far away from the epicentre as West Bromwich which were set for normal earthquakes were dislocated appears to show that the surface waves L and M as distinct from the body waves P and S were of very large amplitude, indicating the release of a tremendous amount of energy from a normal or shallow focus. This also appears to be confirmed by the relatively quick decrease of destructiveness in all directions moving away from the epicentral area. The news from Istanbul Observatory also appears to indicate that the greatest focal depth of any one shock was sixteen miles.

The principal shock is estimated to have shaken the devastated area for a period of some twenty seconds, though seismograms from distant observatories occupy a much longer period of time on account of the variation in velocity of the different waves sent out by the earthquake. The epicentre of the principal shock appears to have been near latitude 40° N., longitude 38·5° E. and the initial time of the first shock about 1.57 a.m. local time (East European) or 26d. 23h. 57m. G.M.T. It must not be thought that all the seven or more shocks originated at the same time or from the same epicentre, as there is evidence to support the hypothesis that the epicentres of the shocks wandered east and west along latitude 40° N., the first being some seventy miles east of Ankara, and later southwards along approximate longitude 39° E. Also it appears to be more correct to speak of an epicentral area rather than an epicentrial point. Aftershocks have continued to be numerous and severe. These, too, appear to be peripatetic along the lines above mentioned, and as yet the diminution according to the usual exponential law does not seem to have become evident. Shocks were still occurring up to December 31, and on that date a violent shock was reported at Bergama, on the Ægean coast.

On December 31, serious floods followed the earthquakes. These have caused further casualties and damage to houses and communications. It is now estimated that the entire population of Erzinjan, Trebizond, Tokat, Sivas, Ordu, Samsun and Amasia, totalling about two millions, are without shelter.

More than five hundred villages in the Brusa region have become marooned, and the Izmid Gulf area is totally submerged. Intermittent, though less intense, shocks occurred in eastern Anatolia on January 1. On the same day, the towns of Karacabey, Manyas and Yenisehir became inundated by the flood water, and the Rivers Nilafur, Halife and Karadere changed their courses. More villages were marooned later in the day.

It is estimated that the devastated area covers about 15,000 square miles, which is about one twentieth of the country.

A third disaster occurred on January 1, when severe storms broke out over the Black Sea causing serious damage to shipping.

On January 2, the floods became more extensive in western Anatolia, where the Sakarya River overflowed and flooded the Bilecik valley. Light tremors were still occurring.

It has been noticed previously by Dr. C. Davison and the late Prof. H. H. Turner that violent earthquake shocks appear to be followed almost immediately by sympathetic shocks in various parts of the world and often at the antipodes. It may be that at these places where sympathetic earthquakes occur there already existed a state of tension (or compression) in the strata and 'layers' which almost amounted to unstable equilibrium, and that it only needed the trigger action of another shock in lieu of some other factor to release the energy and produce the sympathetic earthquake. The Anatolian shock was particularly violent, and therefore it was no surprise to find earthquakes occurring in other parts of the world. On December 27 about 7 a.m., San Salvador in Central America, near to which there was an earthquake on December 5, experienced earthquake shocks, as did Los Angeles in California on the same day. These are both reported to have been strong shocks, though no damage was reported. Between December 27 and 28, twenty-five earthquakes and earth tremors, two of which were of sufficient intensity to rattle crockery though none did any material damage, shook the gold-mining district of the Rand near Johannesburg in South Africa. On December 27 also, at Tangier, the north African port, deaths were reported as being due to a strong earthquake there. Previously, in 1784, Erzinjan was devastated by a severe earthquake, though the shock does not seem to have been so severe as on the present occasion.

It must be remembered that the whole of Asia Minor is a seismic zone for small shocks, as is seen by the fact that Miss Bellamy has catalogued 280 shocks as having occurred in and around Turkey between 1913 and 1930, though earthquakes in this region appear to have been stronger and more numerous of late (prior to the present shock). On September 22, 1939, two hundred people were reported killed during an earthquake which occurred in the Smyrna district (NATURE, September 30, p. 589). Damage and casualties occurred also in the villages of Pergame, Kotchili and Fotcha. Then so recently as November 23 last, an intense shock destroyed six villages in Anatolia (NATURE, December 2, p. 938), killing forty-three people besides injuring many more.

Further news of the present disaster must await the restoration of communications in the afflicted area, and the careful study of the seismograms in observatories throughout the world.

THE PALAO TROPICAL BIOLOGICAL STATION

BY PROF. C. M. YONGE,
DEPARTMENT OF ZOOLOGY, UNIVERSITY OF BRISTOL

THE history of the investigation of coral reefs reveals the fascination these unique marine communities have exercised over the imaginations of zoologists. One thinks of Darwin at Cocos Keeling, of Dana on the United States Exploring Expedition, of Murray on the *Challenger*, of Alexander Agassiz who sailed over all tropical oceans, of Gardiner and Sewell in the Indian Ocean, of Mayor at the Tortugas and at Murray Island and Samoa, of Crossland in the Red Sea and in Tahiti. In more recent years exploration and description have given place to studies of a more physiological nature, and research has been localized around permanent or temporary marine laboratories. Mayor led the way at the Tortugas and was followed by the Dutch at Batavia, by the Great Barrier Reef Expedition at its temporary laboratory at Low Isles and by the University of Egypt on behalf of which Crossland established the marine laboratory at Ghardaqa in the Red Sea.

Now a new centre of research has been established by the Japanese on Korror Island, one of the Palao (Pelew) group situated in the western Pacific some eight degrees north of the equator. The Palao Tropical Biological Station owes its inception to the activities of the Japanese Society for the Promotion of Scientific Research, the site of the station being selected by Prof. Shinkishi Hatai of the Tôhoku Imperial University, Sendai. The Laboratory, which was opened in April 1935, consists of a series of single-story wooden huts admirably suited for work in the tropics. It is surrounded by water which varies in temperature only between 28° and 31° C. and is rich in coral. Since its establishment a continuous stream of biologists have been sent to the Station from Japan and the results of their work are contained in the pages of the *Palao Tropical Biological Station Studies*, the first volume of which has recently been completed.

The most important sections of this work are concerned with corals. No fewer than 116 species, belonging to 43 genera, have already been identified, and these are listed in a systematic paper by M. Eguchi. This number compares with 117 species of 41 genera recently reported by Umbgrove[1] from the Bay of Batavia, probably the scene of the most intense collecting in the tropical Indo-Pacific.

Dr. Noboru Abe, of the Asamushi Marine Biological Station, contributes a series of papers dealing with the unattached coral, *Fungia actiniformis* var. *palawensis*. The eggs are fertilized while still in the gonad and therein develop into planulæ. These are liberated about the time of new moon every month from September until April, a condition which recalls the similar regular planulation of *Pocillopora bulbosa* recorded by Marshall and Stephenson at Low Isles[2]. Post-larval development is described and figured, the animal being capable of capturing active copepods about the fifteenth day. In a later paper the feeding reactions and nematocysts of this and fifteen other species of corals are described. Valuable observations on tentacular and ciliary feeding are recorded, the general conclusions supporting those of Yonge[3] that corals are specialized carnivores feeding on zooplankton. Ecological studies revealed that this species is widely distributed in regions of still water on sandy areas where it is frequently aggregated in large numbers together. Abe analyses the causes of this distribution in a paper dealing with migration and righting actions. He confirms the observations of Marshall and Orr[4] that Fungia is capable of uncovering itself when buried under sand while he also reveals that it can right itself when turned over. This reaction, as well as uncovering, are due to expansion of the disk tissues high above the underlying skeleton. The same phenomenon has been recorded by Yonge[5] in *Maeandra areolata*, the unattached meandrine which occupies a similar habitat in the Atlantic. The aggregation of Fungia is explained by the action of tidal currents which carry them into areas of still water where sand collects between coral patches. Work on the biology of these unattached corals reveals the great powers of adaptation possessed by Madreporaria.

Abe also describes the expansion and contraction of the polyps of *Caulastrœa furcata* which, like the great majority of reef-building corals, expands only by night. Expansion has no relation to food, zooplankton supplied by day failing to induce it. Abe associates expansion by night with the greater need for diffusion of carbon dioxide when this is not removed by the photosynthetic action of the zooxanthellæ. He found that expansion occurs by day when oxygen tension is low and that of carbon dioxide is high. But actually it is contraction during the daytime—a condition not found in the other Anthozoa—which requires explanation, not expansion by night. Nevertheless Abe has broken new ground in this work which will contribute to the eventual solution of this problem.

In a series of papers on the physiology of reef corals Kawaguti confirms the observations of Yonge, Yonge and Nicholls[6] on the oxygen consumption of corals in relation to its production by the zooxanthellæ, and adds important data on the effect of light on pigmentation and growth. Upward growth of corals is all-important in the formation of reefs, and Kawaguti states that all reef-builders containing zooxanthellæ which he examined showed positive phototropism. The presence of glycogen, small amounts of a reducing sugar and copper in Fungia has been determined by Hosoi. Hayasi has entered the controversy concerning the mode of formation of the skeleton and decided that the calicoblasts are the ectodermal cells themselves, not specialized cells derived from these, which secrete the calcareous lamella, including the organic matrix, as an extracellular product. Other papers deal with animals associated with corals, and include observations by Hiro on the gall-crabs, Hapalocarcinus and Cryptochirus, and on cirripedes which grow on corals. A long paper by Matsuya is concerned with the hydrography and plankton of the waters of Iwayama Bay.

Enough has been said to reveal the range and interest of the work being carried out at the Palao Tropical Biological Station. The work of Prof. S. Hatai has long been known in connexion with his direction of the Asamushi Marine Biological Station and the numerous papers published by him and by his pupils in the Science Reports of the Tôhoku Imperial University. He is sincerely to be congratulated on the work of this new tropical marine station which he instituted and the activities of which he has since directed with such conspicuous success.

OBITUARIES

Prof. Ernest A. Gardner

THOUGH unable latterly to take active part in the studies to which he had contributed much, Prof. Ernest Gardner, who died on November 27, aged seventy-seven years, will be remembered in the University of London as the creator of a vigorous department of classical archæology, and as a stimulating teacher, as well as for his administrative services as Dean of the Faculty of Arts (1905–9 and 1913–15), and as Vice-chancellor in 1923–26. After a distinguished Cambridge career, he went out to Greece in 1886 with a fellowship of Gonville and Caius College, and a Craven Fellowship, as the first student of the newly founded British School of Archæology at Athens, of which he became director in the following year. He had already done a season's excavation at Naucratis with Flinders Petrie and Griffith, and took a leading part, with Montague James, Hogarth, and the present Rector of Lincoln College, in work at Paphos for the Cyprus Exploration Fund. Under his management, the British School soon took recognized place among other foreign institutes in Athens, and began to form the long series of explorers, excavators, and teachers at home, which has continued until the present time.

In 1896 the Yates professorship of archæology at University College, London, fell vacant, and gave Gardner a congenial opportunity. Here too he had to begin with the foundations, and secure for his subject a place in the curriculum. His best-known book, a "Handbook of Greek Sculpture", was published in the same year, and at once became the recognized English text-book: later it was supplemented by a more detailed study of "Six Greek Sculptors". In 1897 appeared his "Catalogue of Vases in the Fitzwilliam Museum", and in 1905 he supplemented the "Introduction to Greek Epigraphy" of E. S. Roberts, the Master of his own college, with a volume on the inscriptions of Attica. Of more general (and in the best sense popular) quality was his description of "Ancient Athens" (1902), published at a moment of pause after rapid and varied discoveries, when it was possible for one who knew the ground as Gardner did to present the results as a comprehensible whole, in the lucid style and with the fine scholarship which marked all his writing.

In the War of 1914–18, though over military age, Gardner put his intimate knowledge of Greece and the Greek people at the disposal of the Admiralty, and as a lieutenant-commander in the Royal Naval Volunteer Reserve, did valuable service at Salonica; in leisure moments bringing together at the White Tower the numerous antiquities found in the British trenches and within the lines. Of these the most conspicuous was a huge Roman milestone, whose inscription beginning *Kaisari Germanico* caused some mirth among the rank and file.

Returning to London, Gardner found many distractions in university affairs, but continued to publish useful books on ancient life and art in Greece, and to take an active part in the proceedings of the Hellenic Society, of the *Journal* of which he had been editor from 1897, while from 1929 until 1932 he was its president. A characteristic and memorable contribution to classical studies was his series of cruises for students of all ages, undertaken when such facilities were rare and not easy to arrange; they brought him into personal contact with a wide variety of acquaintances, and opened what was then a new aspect of classical study.

J. L. MYRES.

Prof. V. R. Williams

WE learn with deep regret of the death of Prof. Vasili Robertovich Williams, professor of soil studies in the Timiriazev Academy of Agriculture, and well known to soil investigators for his important contributions to agricultural science.

Williams was born in Moscow in 1863, the son of an American constructional engineer who had settled in Russia in 1854 and married a Russian lady. He studied at the old Petrovsky Academy of Agriculture and Forestry, to which after a period of postgraduate work in Paris with Pasteur, he returned as lecturer. In 1894 the Institute was replaced by the Agricultural Institute of Moscow and he was appointed assistant professor of soils and agriculture. In 1906 he became director of the Institute, and after the Revolution, when it was reorganized as the Timiriazeff Academy of Great Socialist Agriculture, he was again made director though afterwards a political head was chosen in accordance with the policy then prevailing.

From the outset, Williams's soil work centred around the organic constituents: he never lost his interest in these. Only last August he showed me a colourless crystalline organic substance which he had extracted from the soil and to which he attached great importance. Like other Russian soil workers after the Revolution, he did a good deal of soil surveying and he acquired an extensive knowledge of soil utilization and crop production in Russia. On the applied side his most important activity was his keen advocacy of grass leys in the rotation. Russian agriculture was, until recently, mainly based on variants of the old three field system, fallow, winter corn, spring corn. Williams knew how greatly the agriculture of Western Europe had improved when a clover or grass and clover crop was inserted between the corn crops, and he strenuously urged that this should be done in Russia. The coming of collectivization gave an opportunity for a change of system, and the need for increasing the animal population after the devastating losses of livestock at first incurred furnished the justification for strenuous efforts to ensure ample production of fodder crops. So Williams used all his great influence in the U.S.S.R. to extend the culture of grasses and clovers and showed that, not only would more cattle food be produced, but also the soil fertility would be increased and the danger of erosion lessened.

In his later years, Williams devoted much time to the building up of his soil museum, and on each of my recent visits to the Institute he personally demonstrated its chief features: it included a large number of typical profiles with specimens or illustrations of the flora native to each type, and charts showing the most suitable kind of agriculture.

His soil work is described in his book, "Soil Science", first published in 1914 and revised in 1920.

Williams was afflicted with a paralysis which impeded his activities but never damped his enthusiasm. Like others of the older school of Russian scientific workers, he had a good knowledge of a Western language so that conversation and discussion were always easy. In his case the language was English, learned from his father and never forgotten. His work was much appreciated in Russia and he was given the highest awards open to Soviet citizens: the Order of Lenin, a seat in the Supreme Soviet, and membership of the Academy of Sciences; more important still, the deep respect, softened by affection, of many past students now engaged in agricultural organization in Russia. One of the pavilions of the great agricultural exhibition at Moscow is adorned with a very large mural painting showing him at work in his department.

E. JOHN RUSSELL.

Mr. G. Eumorfopoulos

WE regret to record the death at the age of seventy-six of Mr. George Eumorfopoulos, which took place on December 19. Eumorfopoulos had long been known as a great collector and skilled connoisseur of objects of Oriental art and more especially of the art of the Chinese.

George Eumorfopoulos was born in Liverpool in 1863. Until 1934 he was a member of the well-known firm of Ralli Bros. His career as a collector began with English and Continental porcelain, but he soon turned to Oriental art, and was one of the first collectors to give special attention to pieces of the earlier Chinese dynasties—Chou, Han, T'ang and Sung. In this field his collection for the beauty, rarity, and historic and archæological value of the specimens it contained, ranked among the greatest in the world. It was thrown open with the greatest liberality to students, fellow-collectors and connoisseurs from any and every part of the world without distinction beyond interest in that field, which Eumorfopoulos by the judicious use of his wealth in the service of his knowledge and his artistic judgment had made peculiarly his own.

Above everything Eumorfopoulos was anxious that so far as was possible others less fortunate than himself should share in the advantages for study that he enjoyed. A type collection of Chinese porcelain was formed by him and presented to the Museum at Athens, and his gifts to other museums were both numerous and valuable; but his greatest sacrifice was unquestionably the sale of his collection as a whole, which through his generosity in accepting a price far below its pecuniary value, became the property of the British nation in 1935. Now, though divided, it forms by far the most important part of the material available for the study and appreciation of the art of the Far East in the national collections.

Eumorfopoulos was also a generous supporter of all forms of archæological investigation, but more especially if it showed likelihood of advancing knowledge of the history of art. As Sir Leonard Woolley has recalled, he was a generous contributor to the funds for the excavation of Ur; and a visit to the site of the excavation was one of the few occasions on which he travelled in the East. Another which afforded him an even greater delight than that he experienced in Mesopotamia was when in 1935 he travelled in China with R. L. Hobson of the British Museum to help in selecting exhibits for the International Exhibition of Chinese Art held in London in the following winter. The welcome he then received in China was such as befitted his eminence as a collector and expert, and was in a sense the crowning reward of his career.

WE regret to announce the following deaths:

Prof. Czeslav Białobrzeski, professor of theoretical physics in the University of Warsaw, recently executed by the German authorities in Poland, aged sixty years.

Sir John Withers, M.P., who has represented the University of Cambridge in Parliament since 1926, a former president of the Alpine Club and member of the Mount Everest Committee, on December 29, aged seventy-six years.

Prof. Hans Ziemann, professor of internal medicine in the University of Berlin, aged seventy-four years.

NEWS AND VIEWS

Seventy Years Ago

ON November 4, 1869, the first issue appeared of a new "weekly illustrated journal of science" entitled NATURE. It was under the able and forceful editorship of Sir Norman Lockyer, who secured the support of the leading men of science of the day for the new venture. Turning back in thought to those days, it will be seen that there is a certain parallelism between world affairs of that time and the present international situation. Prussia had defeated Austria and its German allies, and had emerged as a leading European power. Strategic railways had been built to the eastern and western frontiers, and tension between Germany and France increased until in July 1870 war was declared. The campaign was relatively short, but its consequences were momentous and have determined much of the history of the past half-century. It seemed worth while, therefore, to turn back to the early pages of NATURE, to note the reaction of scientific men and affairs to the course of events, and to observe the progress of science as recorded week by week in this journal. Let this be sufficient reason for the column of quotations and notes, taken from the first number of NATURE to appear in 1870, which is printed elsewhere in this issue (p. 41). It is proposed to publish week by week similar extracts from the issues of NATURE of "seventy years ago", in the hope that scientific workers will derive both profit and pleasure from these contemporary accounts of scientific thought and events.

Royal Meteorological Society: Symons Gold Medal

THE decision of the Council of the Royal Meteorological Society to award the Symons Gold Medal for 1940 to Dr. J. Bjerknes will be very popular among British meteorologists, to whom he has become well known during his frequent visits to this country. In 1932 the Medal was awarded to his father, Prof. V. Bjerknes, and it is fitting that the son, who shared the work, should also share the honours. Dr. J. Bjerknes is well known for his numerous and penetrating memoirs on the structure of barometric depressions and on the mechanism of the atmospheric circulation. Among his earlier papers we may mention "On the Structure of Moving Cyclones" (1919), and (with H. Solberg) "Meteorological Conditions for the Formation of Rain" (1921), and "The Life Cycle of Cyclones and the Polar Front Theory of Atmospheric Circulation" (1922) in which he laid down the principle of 'cyclone families' and emphasized the role taken by depressions as an integral part of the exchange of air between high and low latitudes.

Later, while temporarily on the staff of the British Meteorological Office, Dr. Bjerknes compiled "Practical Examples of Polar-Front Analysis over the British Isles in 1925–6", published as Geophysical Memoir No. 50, and he has since analysed in great detail, on the bases of both surface and upper air observations, a number of depressions presenting special features. In 1933 the accumulated research of the Norwegian school of meteorologists into the dynamics of the atmosphere was published in book form under the title "Physikalische Hydrodynamik" by V. and J. Bjerknes, H. Solberg and T. Bergeron. Dr. Bjerknes is still young, and we look forward to further important research in future from these brilliant Norwegians.

University of Oxford: Chair of Forestry

MR. H. G. CHAMPION has recently been appointed to fill the chair of forestry at Oxford in succession to the late Prof. R. S. Troup. Mr. Champion graduated at Oxford with first-class honours in chemistry and botany. He went out to India in the Forest Service in 1915 and was posted to the United Provinces. After successful work in divisional and working plans posts he was selected for appointment as sylviculturist at the Forestry Institute at Dehra Dun. In this post he carried out some notable work. Perhaps Mr. Champion's most important contributions to sylvicultural research in India and Burma were a "Sylvicultural Research Manual for India", in two volumes—"The Experimental Manual" and "The Statistical Code"—and a "Preliminary Survey of the Forest Types in India and Burma".

The opening paragraph of the "Research Manual" is testimony to Mr. Champion's methods—"Research work ought never to be hampered by compulsory adherence to any prescribed methods of investigation or of recording. This does not, however, prevent the research worker from receiving considerable aid from the results of his own experience and that of others". This dictum he illustrated in his "Problem of the Pure Teak Plantation", which included valuable notes supplied by the Forest Research Institute of the Dutch East Indies. Other monographs published were notes on *Pinus longifolia*; contributions towards a knowledge of twisted fibre in trees; the importance of the origin of seed used in forestry; rejuvenation and management of sal (*Shorea robusta*); and a "Manual of Indian Sylviculture" (with Sir Gerald Trevor). In addition to visiting all parts of India and Burma as sylviculturist, Mr. Champion was asked by the Government to advise on the management of the Ceylon forests. He visited North America, Japan and Malaya to study local forest soil conservation problems, and saw something of the Kenya forests on his way home on leave in 1939.

Prof. W. P. Jorissen

The Netherlands Chemical Society announced on December 23 that Prof. W. P. Jorissen is retiring from the editorship of the *Chemisch Weekblad* after serving that journal for thirty years. Although Holland is a small country, it has for many centuries been to the fore in the advancement of science, and Prof. Jorissen, who celebrated his seventieth birthday on November 11, 1939, will rank as one of the country's most distinguished chemists. Since his first paper in 1894 dealing with the oxidation of phosphorus, he and his collaborators have contributed many papers from the laboratory for physical chemistry at the University of Leyden. The most important of these deal with his detailed study of the regions of reactions among gases, and even among solids, and with the physical chemistry of explosions (notably the limits). In addition to his academic and research activities at Leyden, Prof. Jorissen, who is an excellent linguist, was editor-in-chief of the *Recueil des travaux chimiques des Pays-Bas* as well as of the *Chemisch Weekblad*. This brought him into lasting contact with the many British chemists who have had occasion to contribute to this Netherlands monthly journal, which publishes communications in French, German and English. We join with his Netherlands colleagues in wishing Prof. Jorissen a long and happy retirement.

Parliamentary and Scientific Committee: New Chairman

At the last general meeting of the Parliamentary and Scientific Committee at the House of Commons, Captain L. F. Plugge, M.P., was unanimously elected chairman. Captain Plugge is a science graduate of the University of London and also of the University of Brussels. During the War of 1914–18, when serving with the Royal Naval Air Service, he was the Admiralty representative at the National Physical Laboratory at Teddington. He also served on the directorate of Aeronautical Research at the Air Ministry under Sir Robert Brooke-Popham, when he evolved in collaboration with Dr. Thurston the design of the first military aeroplane constructed entirely in metal to be built in Great Britain. He has been a fellow of the Royal Aeronautical Society since 1923, and was responsible for the Society's glossary of aeronautical terms (French translation). His work on wireless, which has covered the last fifteen years, is well known, and he is an authority on matters relating to broadcasting.

The University of Cracow

Expressions of sympathy have been received by the Polish Ambassador in Great Britain from universities in Great Britain, the Association of University Teachers and the Universities Bureau of the British Empire in reply to a statement concerning German activities in connexion with the University of Cracow (*The Times*, Dec. 22). It appears that the members of the teaching staff of the University were invited to attend a conference at which the German attitude toward Polish men of learning was to be explained. The tone of the address offended the audience, who walked out, to find lorries waiting outside, in which they were removed and sent eventually to a concentration camp in Germany.

It is stated that 160 members of the University are involved, including Prof. Kazimierz Kostanecki, a former president of the Polish Academy of Sciences, and Adam Krzyzanowski, a distinguished economist, who has since died. A message from the University of Leeds contains the following passage: "The members of the Senate of the University of Leeds . . . desire to place on record their strong condemnation of an action which can have no military justification and must be regarded as part of a deliberate and wanton attempt to destroy the culture and learning of the Polish peoples." We are sure that readers of Nature will be in hearty support of this view.

The University of Birmingham

The University of Birmingham has settled down to war conditions more smoothly than was anticipated, thanks largely to the recruiting policy of the Government whereby some of the deplorable errors of the War of 1914–18 in the waste of ability of university students have been avoided. The number of students in some departments has actually increased, and in the department of medicine in particular the number of full-time freshmen has reached a total of forty-four more than that of last year. The Nuffield Physics Extension Block is nearly ready for occupation, but the exigencies of war-time have unfortunately interrupted the building of Prof. Oliphant's large cyclotron, which is to be the chief feature of the new block.

The new gymnasium of the University also is nearly complete, and it is hoped that it will be used in the near future for physical training. The plans for extension of the Students' Union have had to be dropped for the present. Extra-mural work under the Joint Committee of the University and the Workers' Educational Association has made progress and the number of classes and students has increased. Prof. W. K. Hancock has been given leave of absence to visit West Africa for a study of West African problems in continuance of his "Survey of British Commonwealth Affairs". Dr. O. Frisch of Copenhagen has been appointed a temporary member of the staff of the Physics Department.

Social Services for Youth

THE Board of Education has directed attention to a serious deficiency in our social services in a circular recently issued to the local education authorities for higher education in England and Wales, and a similar circular has been issued by the Secretary of State for Scotland to the education authorities in Scotland. These authorities are asked to take steps to set up local youth committees in their areas, and voluntary organizations and education authorities are called upon to combine in making real provision for the social and physical development of young persons between the ages of fourteen and twenty who have ceased full-time attendance at school. This neglected and elusive problem has been accentuated by war conditions—the black-out, the strain and disorganization of family life—and the Board of Education has now assumed a direct responsibility for juvenile welfare. The National Youth Committee has been appointed to advise them and a special branch of the Board of Education office has been organized to deal with grants and other administrative duties.

The new committees will place youth work on an equal basis with the rest of education. Sometimes they will be sub-committees of local authorities; others may represent all local interests including the local authority. Their task will be to work out an ordered policy, meeting both the immediate needs and indicating the lines of advance under more favourable conditions. Local education authorities are expected to see that the Committee is properly staffed and equipped with office accommodation, and they can assist financially by making grants towards the rent of buildings, salaries of full-time leaders, upkeep and maintenance of premises, including provision of equipment and instructors. The appointment of the National Youth Committee has been welcomed by the King in a message to the Prime Minister, in which His Majesty appeals to the public for volunteers to undertake the tasks of leadership and organization which these plans envisage, and an announcement asking for volunteers has already been made by the President of the Board of Education and the Secretary of State for Scotland at the request of the National Youth Committee.

American Psychologists in War-time

AMERICA believes in being forearmed. Already the American Association for Applied Psychology has devised a plan to mobilize psychologists to aid the Government in time of emergency as they did in 1918 (Science Service, Washington, D.C.). The chief problems to be considered are connected with the selecting and classifying of men according to their abilities, the selecting of promising recruits for military flying, treating those who break down under the strain of war and discipline, and keeping up the morale of armed forces and those at home. The human element and human 'nerves' are much more important now than in the War of 1914–18, although even then a considerable proportion of war casualties were 'nervous' cases.

At the meeting which discussed the matter there were representatives of the Army and Navy, the Public Health Service, and the Department of Justice. The armed services have already arranged to avoid in any future war the heavy psychological casualties of the last war. The first step has been to provide for the careful psychiatric examination of all new recruits, with an observation period in which any border-line cases might be weeded out or assigned to jobs where personality difficulties will be at a minimum. They are also discussing whether, by means parallel to those used by enemy agents to foment discord, psychologists could be used to promote good feeling and smooth out grievances.

Aquaria Societies' Difficulties

THE wartime difficulties of aquaria societies, especially those which maintain public aquaria, have not proved so disastrous as at first expected. The Scottish Aquarium Society, at a recent meeting, decided to produce a modified edition of its journal *Scottish Aquarium Herald*, as Mr. R. Kerr, the original editor, is serving in H.M. Navy. Brighton Aquarium recently acquired an attractive exhibit of 120 silver whiting (*Gadus merl angus*), as well as congers, anglers, spider crabs, ocean sunfish and an owl fish. The Carnegie Aquarium at Edinburgh is also managing to keep a full stock of exhibits, including herring. Manchester Zoo Aquarium has 41 specimens of *Neon tetra* on view in the tropical section, as well as a large electric eel. Dudley (Worcestershire) Zoo Aquarium recently received some claw-footed toads.

On the Continent, Paris Zoo Aquarium has distributed its fish to the Prince of Monaco's Aquarium at Monte Carlo and to private individuals, and its reptiles to Marseilles Zoo. The aquarium at Berlin Zoo has been broken up and closed and the reptiles destroyed. Hamburg Zoo has disposed of all its collection. Belle Vue (Manchester) Aquarium and Vivarium Society has decided to levy half the normal subscription and review the position again in six months' time.

Archæological Discoveries of 1939 in Ireland

ARCHÆOLOGICAL excavations in the vicinity of Lough Gur, Co. Limerick, in the season 1939, it is claimed in a report in *The Times* of January 2, have obtained results of outstanding significance for Irish archæology. This area has now been under investigation for four consecutive seasons, thanks to the Government's scheme for the relief of unemployment;

R 275

and several sites have been examined, including three stone circles, a megalithic tomb, and a series of dwelling sites. The excavations have been carried out under the direction of Prof. Seán P. O'Riordain of the University of Cork. The principal site excavated in 1939 was a large and exceedingly well-preserved stone circle on the western side of the lake, near the Bruff-Limerick road. Not only is this the best known prehistoric monument of the Lough Gur, but it is also said to be the finest stone circle in Ireland. It is built of large stones backed up by a huge bank of earth, and encloses a level, open internal space 155 ft. in diameter.

Here important finds of pottery were made, of which some afford evidence for a new chapter in Irish archæology. A reconstructed vessel proved to be a 'beaker', the first of its kind to be found in Ireland. It belongs to the class of ceramic characteristic of the 'Beaker Folk', who reached Britain in the late neolithic or Early Bronze ages, but, it has been thought hitherto, did not reach Ireland. A further discovery of considerable interest is that of neolithic pottery of types found only sporadically in Ireland, except in the north-east. On the evidence of the finds, the circle is dated at approximately 1700 B.C., and its ritual purpose, that of a prehistoric temple, is regarded as definitely determined. In a group of neolithic houses on the peninsula of Knockadoon in Lough Gur, one, exceptionally well-constructed, is said to be the earliest house yet found in Ireland. It is 32 ft. long by 18 ft. wide. The lower part of the walls is of stone, the superstructure of wood and thatch—a type well known from various periods in northern Europe.

Landscape Meteorology

MR. L. C. W. BONACINA's paper entitled "Landscape Meteorology and its Reflection in Art and Literature" (*Quart. J. Roy. Meteor. Soc.*, 65, No. 282; October 1939) is a detailed study of the scenic aspect of. clouds and weather, and an example of that co-operation between science and art which is one of the most interesting developments of culture during recent years. We welcome particularly the author's dictum that it is a mistake for the man of science to regard scenic values as altogether outside his province. It is equally to the point that the landscape artist will find additional enjoyment, and possibly also increased efficiency, if he studies the physics of meteorological effects. The later part of the paper is mainly devoted to descriptions of local and seasonal phenomena. One outstanding example is that of the night sky as seen from the high plateau of Bolivia, where the general aspect of the constellations is that of coloured stars.

Valuable as is this elaborate paper, the reader cannot help feeling how great is the difficulty of bringing the artistic and scientific aspects of a subject into one essay. The perceptive and reflective moods are alternate, and the literary technique for their simultaneous treatment has not been fully mastered. Indeed, we do not yet know if it can be mastered. If so, it will be by Ruskin re-incarnate in the world of to-day, with the same faculties of sight and expression but imbued with the culture of the present time.

Malnutrition in South Africa

AN informative survey of the state of nutrition of the peoples of South Africa is given by Ellen Radloff and T. W. B. Osborn in a pamphlet with the above title (Johannesburg: The Witwatersrand University Press, 1939. 2*s*.). South Africa has been spoken of as the most prosperous country in the world, which is a true statement for a minority of the European section. But South Africa is also a country of poor whites and poorer blacks, which is true for several millions of non-Europeans and several hundred thousands of Europeans. The principal dietary essentials for proper nutrition are discussed, with descriptions of the conditions that result when these are deficient. Tables are given of the vitamin content of common foodstuffs and of typical South African diets.

The basic ration scale recommended for adult Europeans at the Health Department's institutions appears to be ample and adequate, and is in striking contrast to the daily diet scale for adult native paupers in Cape Province, which consists of 1 oz. of fat (not butter) and 24 oz. of mealies. Remedies are suggested for the malnutrition that exists, which include improvement of the economic condition of the people, educating them to buy meat, milk, fruit and vegetables, and in rural communities providing more land for them to buy and improving their grade of cattle. A direct pharmacological approach to the question is also suggested by providing rations of essential salts and vitamins.

Underground—and the City of the Future

IN the *Beama* journal of November reference is made to Le Corbusier's city of the future consisting of dwellings, offices, and factories contained in huge blocks separated by gardens. One of the main features of this modern city is the large part of its activity which takes place underground. Power stations, garages, warehouses and other public service buildings, as well as traffic routes for vehicles and pedestrians, would be constructed in this way. Already there exists a plan for the diversion of a large part of the Paris traffic, the underground routes for which were examined by the Minister of Public Works some years ago. *Électricité* published a report on this subject by M. Roger d'Arboville, professor of applied electricity in the well-known École spéciale d'Architecture, on the lighting of underground traffic and pedestrian routes. He reviews the practice exemplified in some of the short subways in Paris, in the long road tunnel projected for 1941 under the Meuse, the mile-long roadway under the Escaut at Antwerp and various railway tunnels in France and England.

M. d'Arboville discusses the question of the lighting of underground road tunnels both in actual road tunnels and in many tunnels which are projected. The ever-increasing density and speed of road traffic make this question of great importance, especially at the entrances to the tunnels. The light conditions at these places must be very carefully graded or else the speed of all transport entering the tunnel must be heavily stepped down. The latter course is objectionable as it interferes with the normal flow over a wide area. He suggests that photo-electric cells might be used to maintain the lighting more constant and so overcome the changing variations of natural light. The photo-cells should be directed towards the ground, since otherwise the effect of sunlight variations is too strong.

Dismantling an Old Colliery

WE learn from an article in *Roads and Road Construction* of December 1 that the famous Cymmer Colliery at Porth, Glam., from which coal has been raised for more than a hundred years, has recently ceased work. The immense quantity of plant which it contains is to be dismantled and made available for use either in the coal industry or in similar industries engaged on contracts of national importance. In the history of this colliery, which once employed more than three thousand men and produced more than three thousand tons of coal a day, an interesting story is told of how about fifty years ago, whilst boring in the shaft for piping supports, the men struck what is called a 'gas blower', which is a sort of pocket of free gas. In these days men were permitted to take naked lights down in the cage with them so that they could heat their tea, and one of these lights ignited the natural gas. As it was dangerous to allow such gas to escape into the shaft, a two-inch pipe was installed to conduct it to the surface. Here it has been burning for fifty years without being extinguished. Measurements show that approximately 650 cub. ft. per hour was being emitted at the 'blow'. The gas is chiefly methane, and arrangements have now been made to 'bottle' it in steel cylinders at about 800 lb. per sq. in. pressure for scientific and industrial use.

Messrs. George Cohen of London and Swansea are at the present time running a 5,000 cub. ft. vertical engine-driven compressor now in the mine to supply air to the haulages for removing the underground plant and machinery, of which there is no less than 4,000 tons, including about 1,200 tons of pit rails. Compressed air was also supplied below for working coal-cutters, jigger conveyors, belt conveyors, and turbine fans. Electric light, both for underground and surface, is supplied by steam-driven generating sets. In 1933 a modern dry coal cleaning plant of 75 tons per hour capacity was installed at a cost of about £20,000 by the Birtley Iron Co. The roads to the pit are in excellent condition, being supported by about 1,700 tons of steel arches, of which Messrs. Cohen expect to recover about 500 tons.

Hydro-Electric Development in India

RECENT reports from India, referred to in *Beama* of November, state that a very large irrigation scheme which will include the generation of large quantities of electric power between the Punjab and the State of Bilaspur is under construction. The volume of water that will be impounded is three times as large as that of the Aswan dam across the Nile. A further scheme for the development of water power utilizes the high run-off of the monsoon rains from the High Range Hills to the plain at Travancore in southern India. Power is obtained from the Munnar River as it descends in a series of cascades from the hills. The monsoon waters are impounded in storage reservoirs built on natural sites. The power station is built on the banks of the river, with the tail-race planned to discharge into it. Above stream, the river water is decanted by a weir, then passes through a channel to the tunnel and forebay. From there it is carried in a 10,000 ft. long tunnel an open channel was impracticable owing to the crumbling nature of the surface rock—to the surge tower. Two parallel pipe-lines connect with the power house, each supplying water to a 6,000 brake horse-power turbine.

Weather by Telephone in New York

ACCORDING to the *Bell Laboratories Record* of November, the New York Telephone Co. inaugurated a new service last April. It is now possible in the Metropolitan area to dial 'weather', and hear the latest weather prediction, including the anticipated temperature, winds, and rain or snow conditions. The bulletins are based on direct teletype reports from the United States Weather Bureau ; at present these reports are changed hourly between seven in the morning and eleven at night. When important changes occur, special bulletins may also be given. All the equipment used for this service is installed in the West Fiftieth Street Central Office building, and weather announcing trunk lines are run to all the central offices in Manhattan, while other parts of the metropolitan area reach the announcing bureau through subcentres or tandem offices. In the time-announcing system a special operator makes each announcement herself. In the weather system use is made of a recorder using magnetic tape. It is well suited for this service as it is necessary to change the recorded message frequently and permanent preservation of the record is of no importance.

The record is made in the usual way by producing, in a moving steel tape, a magnetic pattern corresponding to the voice current coming from the microphone circuit. This pattern remains in the tape and can be 'picked up' electrically many thousands of times before being erased. This is done by saturating the tape with a strong magnetic field. The entire process of erasing, recording a new message and reproducing is controlled by a few keys in the operating turret. No experience or technique is required to obtain exact reproduction of the announcement, and since the steel tape can be used again and again indefinitely, there is no continuing expense for record material and no processing cost involved. Three of these machines are used. The tape machine employs slightly more than 40 ft. of tape wound on three brass drums. The two ends of the tape are electrically welded so that it forms a single tape loop.

Demography of Canada

According to the report recently made to the International Office of Public Health (*Bull. Off. internat. d'hyg. publ.*, 31, 1678; 1939) by Dr. H. B. Jeffs, the delegate for Canada, the population of Canada, exclusive of Yukon and the North Western Territories, amounted to about 11,106,000 on June 1, 1937. The marriage-rate for 1937 was 7·9 per 1,000 inhabitants. The highest percentage of marriages was registered in Manitoba (8·5) and the lowest in Saskatchewan (6·2). The birth-rate was 19·8 per 1,000 inhabitants as compared with 20·0 in 1936. The total number of live births was 219,988 in 1937, as compared with 220,371 in the previous year. The highest birth-rate was in the province of Quebec, where 75,635 births were registered or a rate of 24·1 per thousand inhabitants. In 1937, 113,694 deaths were registered in Canada or a mortality of 10·2 per 1,000 inhabitants, as compared with 9·7 in 1936. The total number of deaths of children under one year of age was 16,675 or a mortality of 76 per 1,000 live births as compared with 66 in 1936. The maternal mortality was 1,067 in 1937 or a mortality of 4·9 per 1,000 live births, as compared with 1,233 deaths or a rate of 5·6 in 1936. The highest maternal mortality was in Prince Edward Island (5·8 per 1,000 live births) and the lowest in Nova Scotia (2·7 per 1,000 live births).

A New Biological Journal

Under the title of *Lloydia* the Lloyd Library of Natural History, Cincinnati, Ohio, has commenced the publication of a new quarterly journal of which the first number appeared as Vol. 1, Nos. 1–4, 1938; the date of publication is given as January 7, 1939, but a copy has only just reached Nature. The subscription rate is three dollars per annum. The editor is Theodor Just. From the numbers already published, the main field of the new journal would seem to be systematic, but papers dealing mainly with structure have been published and many of the communications have been freely illustrated with both drawings and photographs. Manuscript contributions are welcomed, as also exchanges with other institutions. Communications should be addressed to the Librarian, Lloyd Library, 309 W. Court Street, Cincinnati, Ohio.

Bibliography of Seismology

The *Bibliography of Seismology*, 13, No. 2, published by the Dominion Observatory at Ottawa, has just been received. It contains 124 items over the period April, May, June 1939, and has been compiled with the assistance of collaborators in Canada, United States, New Zealand, Italy, Germany, Norway, Japan, U.S.S.R., France, Holland and England. As in the preceding number, in addition to works on pure seismology, there is again a considerable number of works listed on applied seismology, chiefly concerned with geophysical prospecting. A list of patents concerned with this latter contains eight items, five being United States patents, one Canadian, and two U.S.S.R. It is pleasing to see a considerable number of papers listed from the Seismological Institute, Academy of Sciences, U.S.S.R., though it would add to the value of these Russian works if the authors supplied translations or abstracts in French, German or English. Unfortunately, again South America is not represented.

Earthquake in Central America

An earthquake of considerable intensity was experienced on the Pacific coast of central America on December 5 just after 8.30 G.M.T., though no damage has been reported. The shock was recorded on practically all the seismographs in America; at De Bilt (Holland), where the preliminary waves arrived just after 8.42; and at Kew, where a full complement of waves including P_cP, *SKS* and *SSS* were readily discernible. The maximum ground displacement at Kew was 0·043 mm. From readings of seismograms at adjacent stations, the epicentre has been determined by the United States Coast and Geodetic Survey to have been in the Pacific Ocean some twenty miles due east of Rio Suchiate (Guatemala).

Announcements

The U.S.S.R. Academy of Sciences has marked the sixtieth birthday of M. Joseph Stalin by electing him an honorary member of the Academy, nominally in recognition of his contributions to the development of the social theories of Marx and Lenin. It should be noted that even the ordinary membership of the Academy is restricted to a limited number of men of science of outstanding repute, while there are very few honorary members, all of them hitherto being scientific men of international fame.

Prof. Fritz Lejeune, of Cologne, has been appointed professor of the history of medicine and director of the Institute of the History of Medicine at Vienna.

The Italian Minister of the Interior has offered a prize of 30,000 lire for the discovery of chemical or biological substances to take the place of insulin.

The League of Nations Health Committee has arranged to set up a sub-committee which may be summoned in an emergency to deal with epidemics of infectious diseases arising out of the War.

The Ministry of Health has published a memorandum on typhoid fever for the use of local authorities and medical officers of health (Memo. 225/Med. H.M. Stationery Office. 2*d.* net). The memorandum deals with typhoid and paratyphoid fevers, their history, diagnosis, prevention and control, and it contains an appendix on laboratory methods of diagnosis.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 32. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

A Factor influencing Nitrogen Excretion from Leguminous Root Nodules

THE excretion of nitrogen compounds from leguminous root nodules which has been demonstrated in this laboratory with a sterile culture system and, from the practical point of view, investigated with ordinary pot cultures, has not been shown in the pot cultures of all investigators[1,2]. With a sterile culture system Wilson has accomplished the excretion almost regularly[3].

It is difficult for us to explain the negative results appearing in the literature since, during 1928–38, we have regularly obtained excretion, and often a very powerful one, in hundreds of experiments also with pot cultures. In 1938 and 1939, however, excretion occurred only in a part of the experiments. Of parallel cultures under the same conditions, some showed powerful excretion while little or no excretion occurred in others. Light intensity could therefore not be the cause of conflicting results, as the plants were growing under identical conditions. There was also no difference in the quality of the quartz sand used in them.

In trying to discover the cause of these variations we finally paid attention to the quality of the containers. We have always used unglazed pots of burned clay. When we examined the pots used in the summers of 1938 and 1939 we noted great variations in their porosity. The pots in which oats grew fairly well in association with inoculated peas proved to be more porous than those where the growth of the oats was poor. The porosity of the pots was measured by allowing them to soak in water and determining the time which was required to make the inside of the pot moist. The accompanying table illustrates some of our results.

* Unglazed burned clay pots, diam. 9 in., 7·75 kgm. quartz sand, 4 peas (inoculated with bacterial strain *H X*) and 6 oats (Guldregn II) in each pot. Control: 6 oats alone. N-free nutrient solution. Period of growth: 20 July–25 Sept. 1939. 3 parallel experiments.

Variety of pea	N in peas, mgm.	N in oats, mgm.	Excreted N taken up by oat, mgm.	Soaking time of the pot, min.
Adoptive	172·2	69·6	55·2	33
	100·8	40·9	26·1	31
	187·6	24·1	9·3	105
Concordia	204·3	48·2	33·4	20
	439·9	13·4	− 1·4	80
	247·6	32·5	17·7	25
Marmor. Glænö	167·8	74·2	59·4	45
	546·1	17·9	3·1	165
	616·9	13·4	− 1·4	160
Control		15·4		
		14·8 } 14·8		
		14·3		

Our results show that the growth of oats in associated culture with pea depends evidently on the porosity of the culture pot, and thus on the aeration of the media. As the experimental conditions—sand and nutrient solution—have been identical in all experiments, only the difference in the quality of the pots can explain the decided variations in the excretion of the parallel cultures. The experimental data also illustrate the fact noted earlier that when the excretion is high the growth of the pea is often, though not always, impaired.

When the excretion of nitrogen from the leguminous root nodules is investigated in associated cultures with ordinary pot cultures, containers should be clay pots, which are very porous. Large pots generally give better results than small ones.

Effects of Concentrated Aqueous and certain Non-aqueous Solutions of Alkali upon Wool

CHEMISTS are well aware that wool is readily attacked by alkaline reagents. These disrupt the disulphide groups of the cystine contained in the polypeptide chains, thus weakening the fibre structure. The woollen manufacturer also recognizes that wool is susceptible to attack by alkali, as the term 'alkali damage' indicates. This damage frequently results from inefficient scouring which afterwards causes the wool to dye unevenly.

The surprising fact that the fibre is not seriously damaged by cold, concentrated, aqueous solutions of sodium hydroxide was investigated by Buntrock[1], Matthews[2], and Speakman[3]. The two earlier workers showed that yarns, treated with 52 per cent aqueous sodium hydroxide solutions, became stronger. Matthews reported that the sulphur content was greatly lowered by the treatment, that the surface scales of the individual fibres fused together, that the ability of the wool to felt was not reduced, and that its affinity for acid dyes was increased. Speakman showed that the strength of individual fibres was unaffected by this treatment. He suggested that the increased strength of yarns was due to the fusing together of different fibres under the influence of weakly alkaline solutions formed during the processes involved in the removal of the alkali from the wool. Some of these matters have been reinvestigated by us, and particular attention has been given to the removal of the alkali in such a way that risk of damage to the fibres in this process was minimized. A summary of our results follows.

(1) The sulphur and nitrogen contents of merino wools are very little altered by immersion in 52 per cent sodium hydroxide for periods up to 30 minutes at room temperatures.

(2) No major changes in the surface structure of the fibre result from such a treatment for 5–10 minutes. Microscopic examination shows little or no difference between treated and untreated fibres.

(3) Wool treated with concentrated solutions of sodium hydroxide absorbs acid dyes *evenly*. Such wools have a greater affinity for acid dyes than similar untreated wools.

(4) A woven woollen fabric treated with 52 per cent sodium hydroxide shows less tendency to shrink on washing than a normal fabric.

These studies have been extended to the treatment of wool with alkalis dissolved in certain organic solvents. By using much weaker alcoholic solutions of sodium (or potassium) hydroxide, similar results to those obtained with concentrated aqueous solutions can be obtained with less risk of damage to the wool. The reduced tendency of treated wools to shrink, moreover, is much more marked, especially when knitted fabrics are used. This has been found to depend on:

(*a*) The nature of the alkali used. Potassium hydroxide gives slightly better and more even results than sodium hydroxide.

(*b*) The nature of the solvent. Solutions of alkali in dry methyl alcohol give less satisfactory results than similar solutions in alcohols of higher molecular weight.

(*c*) The percentage of water present in the solvent. The results are obtained slowly with dry reagents and quickly if 10 per cent or more of water is present. Damage to the fibre is more likely at these higher concentrations, and the optimum water content for speed of reaction, ease of control and minimum risk of damage is about 5 per cent.

The time of reaction depends on the concentration of the alkali used; thus we have found that with more dilute solutions longer immersion periods are required to give satisfactory results.

The limits that have been found with 7 per cent potassium hydroxide solutions are 1–30 minutes, depending on the water content of the alcohol used, and the treatment period may be extended to 16 hours with similar solutions of 0·05 per cent concentration. The rate of action increases with temperature.

Risk of damage to fibres after they have been treated with alcoholic solutions of alkali is eliminated by neutralizing excess alkali in a bath of 5 per cent, by volume, concentrated commercial sulphuric acid in alcohol. If hydrogen sulphide is evolved during the treatment it indicates that the process has been carried out incorrectly, and the wool will probably be damaged.

As regards strength and ability to stretch, treated fibres are not different from untreated. Their surface, however, is rougher than that of untreated fibres. These physical tests have been made by our colleague, Mr. E. H. Mercer, who has also noted that the more tightly twisted yarns of treated fibres are stronger than similar yarns of normal wool.

This method of treating wool promises to be of importance from both the commercial and the purely scientific points of view. Commercially, a treatment of wool for less than two minutes may give a product which is substantially non-felting, which absorbs dyes more readily, which can be made into stronger yarns, which will wear more satisfactorily than normal wool, and which shows less tendency to develop a fluffy surface during wear. Scientifically, the reagents may prove useful in further study of (*a*) the capacity of wool to combine with alkali; (*b*) the cause of felting and shrinkage resulting from this; and (*c*) the molecular structure of wool.

A full account of our work will be published shortly as a bulletin of the Council for Scientific and Industrial Research. The work has been facilitated by financial assistance granted by the Australian Wool Board.

Amine Oxidase and Benzedrine

EXPERIMENTS which we have carried out during recent years seem to be of general interest in connexion with the observation reported by Mann and Quastel[1] on the effect of benzedrine (β-phenyl*iso*propylamine) on the metabolism of the central nervous system. First, it now seems possible to relate the action of the drug to an *in vitro* effect on one of the enzymic systems in the body; secondly, we can in this instance relate the action of the drug to its chemical structure. The effect on metabolism finds its explanation in the inhibitor action of β-phenyl*iso*propylamine and its derivatives on amine oxidase. This effect was first described for ephedrine[2], but it was shown soon afterwards that ephedrine shared it with all other derivatives of β-phenyl*iso*propylamine that were examined[3]. The general rule emerged from these experiments that substances of the constitution $R—\overset{|}{\underset{|}{C}}—CH.NH_2—CH_3$ act as inhibitors of the enzyme. The characteristic difference between substrates and inhibitors of amine oxidase is that the latter contain the amino group not attached to a terminal carbon atom of a chain. It is known that the awakening effect of these drugs is also bound up with this characteristic structure, and that it is absent from those substances in which the amino group is attached to a terminal C atom of a chain[4,5]

Partly through the kindness of Dr. G. A. Alles, of Los Angeles, I have recently had the opportunity of examining a number of different amines of this group and have shown that a further subdivision of the β-phenyl*iso*propylamine group of inhibitors is possible. Substances of the structure $R—CH_2—CH.NH_2—CH_3$, for example, veritol and benzedrine, are much stronger inhibitors of amine oxidase than those of the structure $R—CHOH—CH.NH_2—CH_3$, for example, ephedrine; a comparison with the awakening properties of these substances in the living animal shows that there is again agreement between *in vitro* effect and pharmacological action[4]*.

Electrophoresis of Animal Viruses and their Neutralizing Antibodies in Low Concentrations

A PERUSAL of the literature dealing with the physico-chemical properties of animal viruses and their neutralizing antibodies reveals the fact that very little attention has been given to the mobility in an electric field of these important substances.

The main investigations on the electrophoresis of viruses and their neutralizing antibodies have been to determine the sign of the charge and the direction of mobility[1,2,3], the separation of virus from virus-antibody mixtures[4,5], and the recovery of virus from the brains and spleens of animals recovered from virus diseases[5].

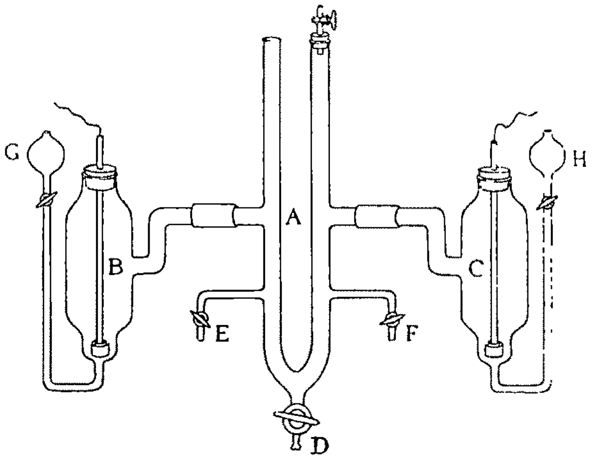
In none of the above-mentioned investigations has any attempt been made to determine the rate of migration of the viruses or their neutralizing antibodies, as the apparatus employed was highly unsuitable for that purpose. In order to measure the migration of viruses and their neutralizing antibodies an apparatus was constructed which has been applied with success to such measurements.

With the aid of the accompanying diagram the essential parts of the apparatus can be explained. *B* and *C* are two electrode vessels connected up to the U-tube *A* in the way illustrated. Two reversible silver–silver-chloride electrodes in saturated potassium chloride solution serve as anode and cathode. The electrode vessels and U-tube are filled with buffer against which the substance has previously been dialysed. By means of the two vessels *G* and *H* saturated potassium chloride solution is let into the electrode vessels to cover the electrodes. The virus or antibody in serum buffer mixture is let through the tap *D* to form a boundary under the buffer solution in *A*. The boundaries are brought up to levels above the two taps *E* and *F*. A position is marked off 2 cm. above the boundaries between the buffer and serum buffer mixture, and the electric current switched on. At the position 2 cm. from the original boundary small samples of fluid (0·1 c.c.) are carefully pipetted off with a fine pipette after suitable time intervals and tested by means of biological methods for virus or antibodies. The limb of the U-tube in which the samples are not taken is kept closed by means of a stopcock. The samples remain negative until the virus or antibodies reach the pipette.

The mobility of the substance investigated is given by the equation[6]

$$\mu = D\,x\,O/tA,$$

where D is the distance traversed by the substance (here 2 cm.); x is the conductivity of the solution; O is the cross-section of the U-tube at the point where the samples are taken; t is the time required for the substance to traverse the distance D; A is the strength of the electric current.



By plotting the mobilities at various hydrogen ion concentrations against the hydrogen ion concentrations of the buffer, the iso-electric point can be determined by extrapolation or interpolation[6]. The experiments are conducted in a room at constant temperature and a small current is employed, generally 1 milliampere, to minimize heating effects which might cause convection currents. It would be more preferable to conduct the experiments in a water thermostat. The apparatus employed is a modification of the Tiselius moving boundary method[6,7], but it is less complicated and less expensive, and with suitable optical arrangements and proper thermostatic control it can be used for similar purposes, for example, separation of the components in protein mixtures.

An extensive report on the electrophoresis of viruses and their neutralizing antibodies will be published in the *Onderstepoort Journal*.

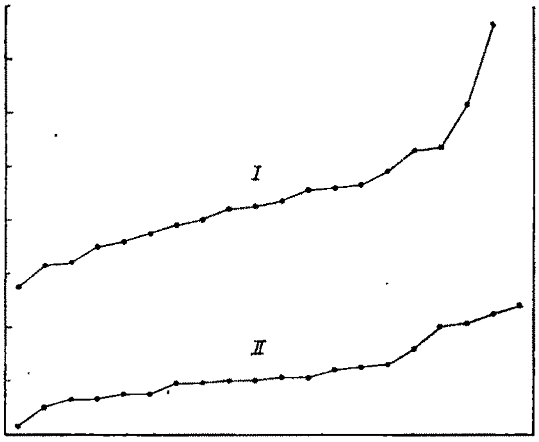
Relation between Corpus allatum and Ovaries in Adult Flies (Muscidæ)

THE adult Muscids examined by me (Musca, Calliphora and Lucilia) possess an unpaired median corpus allatum which is situated dorsal to the œsophagus in the region connecting the neck with the prothorax. Just beneath the corpus allatum lies the aorta, beneath this comes a sympathetic ganglion (ganglion hypocerebrale), and below this lies the œsophagus. An examination of newly hatched unfed females of *Musca domestica* showed the presence of a small rather flat corpus allatum, whereas the same organ of mature females was considerably larger, which was also the case in Calliphora and Lucilia. Thus it seems reasonable to assume that the corpus allatum of adult Muscidæ has a function similar to that of the corpus allatum of the adult female Rhodnius as found by Wigglesworth[1] (cf. also experiments of Weed on Melanoplus[2]), that is, to control the development of the ovaries. In order to test this hypothesis I removed the corpus allatum of rather newly hatched unfed females of Calliphora and Lucilia. It proved possible to extirpate the corpus allatum solely without damaging the aorta. The mortality was low; out of seventeen Calliphora which had their corpus allatum extirpated three died. After six days at 25° C. and normal feeding (sugar, meat and water) thirteen of the fourteen survivors showed small slightly developed ovaries, whereas one had large ovaries with nearly mature eggs. Thirteen of the fifteen operated controls (none of which died) had large nearly mature ovaries, and two had somewhat smaller ovaries with conspicuous nurse cells; but these ovaries were much larger and much more developed than the ovaries of the thirteen individuals from which the corpus allatum had been excised.



RELATIVE AREAS OF CORPORA ALLATA IN CASTRATED CALLIPHORA FEMALES (I) AND OPERATED CONTROLS (II).

Fourteen about one-day-old unfed Lucilia females had their corpus allatum extirpated. After six days at 25° C. and normal feeding, nine showed small slightly developed ovaries; in one fly the ovaries were somewhat larger, two had ovaries with conspicuous nurse cells, and two had large nearly mature ovaries. Out of ten operated controls, one died, the surviving nine all showed large mature ovaries. The small ovaries of the flies without corpus allatum seem to have stopped growth at the same stage of development.

It would appear from these experiments that the corpus allatum of Calliphora and Lucilia females produces a hormone which regulates maturation of the ovaries, just as is the case in Rhodnius.

The growth of the ovaries in some individuals, in spite of the removal of the corpus allatum, may be explained in one of two ways:

(1) Already before the extirpation the corpus allatum has produced sufficient hormone to induce maturation of the eggs.

(2) A small piece of the corpus allatum may have remained in the animal and produced the hormone necessary for maturation of the eggs.

If the first hypothesis is the right one, it should be possible to determine a critical period for the effect of the hormone by using flies the age of which is exactly known. Experiments have been begun to test this.

In dissecting females of Lucilia, four flies were found to possess an abnormally large corpus allatum and very small undeveloped ovaries. According to the known age of two of these flies, they ought to have been mature. Two explanations seem to be possible:

(1) The corpus allatum has hypertrophied, but is functionless, and for this reason the ovaries remain undeveloped.

(2) There is a mutual influence of the corpus allatum and the ovaries. Some unknown factor has inhibited the development of the ovaries, although the corpus allatum still produces the egg-maturing hormone; but the abnormal ovaries have no effect on the corpus allatum, and so this organ hypertrophies.

If the second hypothesis holds true, removal of the ovaries from newly hatched flies ought to cause a similar enlargement of the corpus allatum as that seen in the abnormal individuals referred to. In this connexion it should be remembered that in some vertebrates castration brings about a considerable increase in size of the pituitary gland, an organ to which the corpus allatum of insects bears some resemblance.

To test this, fifty newly hatched Calliphora females had their ovaries extirpated. Out of these, thirty-one died (the mortality was very high at the beginning, later on I succeeded in lowering it considerably); after seven days at 25° C. the surviving nineteen showed an abnormally large corpus allatum. Out of thirty-five operated controls fourteen died; after seven days at 25° C. twenty showed fully mature ovaries and a considerably smaller corpus allatum than the castrated ones, whereas one fly had abnormal ovaries and correspondingly a very large corpus allatum. All the corpora allata of the castrated females as well as those of the operated controls were examined on living animals and drawn by means of a camera lucida. The areas of the drawings of the individual organs have been calculated and are shown in the two curves of the accompanying graph; to obtain the absolute sizes of the organs these values must be divided by 8,100 as the linear magnification used was 90. It is obvious, as one might have expected, that there is a considerable variation in both groups, but in no case is a corpus allatum from a control as large as a corpus allatum from a castrated female.

These experiments support the second hypothesis stated above. It thus appears that not only does the corpus allatum control the ripening of the ovaries in the normal adult fly, but also the growing ovaries influence the size of corpus allatum, which in the absence of ovaries hypertrophies. As yet the precise nature of this action is obscure. The investigation is being continued.

Bending of Glass under Long Continued Stress

I HAVE tried the following experiment: A piece of optically flat crown glass 3·5 cm. long, and 1·5 cm. broad and 0·3 cm. thick, was supported on wood at the extreme ends, and the middle was loaded with 6 kgm. applied by means of a wooden chisel edge, which carried a weight moving in guides above. It remained in position from April 6, 1938, to December 13, 1939. At the end of that time the glass was taken out and tested on an optical flat by means of interference fringes. It was found to have been bent, the sagitta of the arc amounting to 2·5 bands or 1·25 waves, that is, about 6×10^{-5} cm.

Scattering of Mesons and the Magnetic Moments of Proton and Neutron

THE meson theory in its present form exhibits a number of difficulties which are connected with the particular way in which the conservation of charge and the spin enter the interaction between mesons and the nuclear particles. The expression for the anomalous magnetic moment of the proton and neutron[1], for example, diverges as $\int_0^\infty dk$. The cross-section for the scattering of mesons by a nucleus is found to be very much larger than experiments permit and increases rapidly with increasing energy. This would be incompatible with the high penetrating power of cosmic ray mesons. The cross-section for scattering of a longitudinal meson (rest mass μ) with energy ε (momentum p/c) is, according to the present theory, given by[2]

$$\varphi = 4\pi\left(\frac{g^2}{\mu c^2}\right)^2 \frac{p^4}{\varepsilon^2(\mu c^2)^2} \qquad (1)$$

From the analogy of mesons with light quanta, one would expect a cross-section of the order $(g^2/Mc^2)^2$, where M is the mass of the proton, and no increase with energy for $\varepsilon > \mu c^2$. The experiments by J. G. Wilson[3] have shown that the scattering cross-section even for an energy so low as a few times μc^2 (10^8 ev.) is smaller than (1) by an order of magnitude and does not increase with energy.

As can be seen from the computation of (1), both difficulties are due to the fact that the conservation of charge forbids a number of transitions which could occur if mesons were neutral particles[3]. A neutral meson could, for example, be *emitted and absorbed* by a proton. A positive meson can *only be emitted by a proton but not absorbed.* The cross-section for scattering would be of the right order of magnitude if we allow a positive meson also to be absorbed and a negative one to be emitted by a proton, etc., or, in other words, if 'proton states' with charges $-e$ and $+2e$ existed[4]. The introduction of those particles meets, however, with the following difficulties. First, particles of this nature are not observed and are unlikely to have escaped observation if they occur in heavy nuclei. Secondly, if a proton were capable of emitting also a negative meson, the negative meson would give a contribution to the anomalous magnetic moment of the proton of opposite sign and—all other quantities being equal—of the same value as the contribution from the positive meson. Thus, there would be no anomalous magnetic moment at all.

These difficulties can be overcome if we assume that the rest mass of the new particles is considerably *higher* than that of the proton, say, by 25–50 electron masses (see below). The particles would then be extremely unstable and would not play any part in the structure of heavy nuclei. Denoting the mass difference between the new particles and the proton by ΔM, the cross-section for the scattering of a longitudinal meson becomes, for $\varepsilon < Mc^2$, assuming $\Delta M \ll \mu$,

$$\varphi = 4\pi\left(\frac{g^2}{\mu c^2}\right)^2 \left\{\frac{1}{3}\left(\frac{\mu}{M}\right)^2\left(\frac{\mu c^2}{\varepsilon}\right)^4 + \left(\frac{\Delta M}{\mu}\right)^2\frac{p^4}{\varepsilon^4}\right\}. \qquad (2)$$

This expression does *not* increase with energy for $\varepsilon > \mu c^2$. If p is approximately μc^2, (2) is smaller by a factor $(\Delta M/\mu)^2$ than (1). A value $\Delta M/\mu$ of approximately 1/5 would be sufficient to bring (2) into harmony with the experimental requirements. For ε greater than Mc^2, φ will probably decrease owing to the relativistic features of the proton.

Similar considerations must be applied to the spin. The spin contributes also to the high scattering cross-section (for transverse mesons). This can be avoided if we introduce also 'higher spin states', for example, heavy particles with spin s of 3/2. Transitions from the normal proton state, s equal to 1/2, to these higher states under the influence of a meson field can be included in the theory in a very simple manner. In the present theory the spin-dependent interaction between a meson field φ and a nuclear particle is f/λ (σ curl ϖ), where σ is the spin matrix and has only matrix elements for $\Delta s = 0$. σ has to be extended in such a way as to include transitions $\Delta s = 1$. This can be done if we replace σ by the matrix of a dipole moment $\mathbf{r}/r$. For transitions $\Delta s = 0$, the matrix elements of $\mathbf{r}/r$ and of σ are identical. If this is done, the cross-section for the scattering of transverse mesons also is small and of the order of magnitude (2). The physical significance of $\mathbf{r}/r$ is that of the *intrinsic* magnetic dipole moment of the proton, which is a characteristic feature of the meson theory ($\mathbf{r}$ is not, of course, the spacial position of the proton).

As a further result of our new assumptions, the anomalous magnetic moments diverge only *logarithmically*. Such a divergence can, at the present stage of the theory of the meson, scarcely be considered as a very serious difficulty. The relativistic features of the proton have so far been neglected, and it may well be that the logarithmic divergence would disappear if they are taken into account properly. As an upper limit for the validity of the meson theory in the form proposed above, we therefore take the rest energy of the proton. The anomalous magnetic moment of the proton then becomes (in units of the nuclear magneton μ_0)

$$\frac{\mu}{\mu_0}=\frac{16}{3\pi}\,\frac{M\,\Delta M}{\mu^2}\,\frac{f^2}{\hbar c}\left(\log\frac{2E_m}{\mu c^2}-\frac{4}{3}\right),\quad E_m\sim Mc^2. \quad (3)$$

This is of the right order of magnitude when $\Delta M/\mu$ is approximately 1/5, which is the value assumed above.

[3] Wilson, *Proc. Roy. Soc.*, in the press. I am very much indebted to Dr. Wilson for having sent me his MS. before publication.

[4] This possibility was first mentioned to me by Bhabha in a private discussion in connexion with his classical theory for neutral mesons. The whole problem was very much clarified in discussions with Bhabha, Fröhlich and Kemmer.

A Simple Rule for Evaluating Atomic Constants

FROM some of the fundamental constants, natural units can be formed, showing simple relations among many other constants[1]. The fine structure constant is the well-known example

$$\frac{2\pi e^2}{ch}=\alpha=\frac{1}{137} \quad . \quad . \quad . \quad (1)$$

Also α gives a simple relation between the velocity of the electron in the normal hydrogen atom and the velocity of light, and that between the radius of the electron and of the hydrogen atom in the normal state:

$$\frac{v_e}{c}=\alpha,\ \frac{\gamma_e}{\gamma_{\mathrm{H}}}=\alpha^2.$$

Now let us consider the two following length units: one is for charged particles, and the other for uncharged particles:

$$\frac{e^2}{m_e c^2}\equiv l_c \quad . \quad . \quad . \quad (2) \qquad \sqrt{\frac{Gh}{c^3}}\equiv l_u \quad . \quad . \quad . \quad (3)$$

The ratio of these two,

$$l_c/l_u=\frac{e^2}{m_e\sqrt{Gch}}\equiv A, \quad . \quad . \quad . \quad . \quad (4)$$

will be shown to play a similar part to α. In order to show that, let us employ the de Broglie wave equation in a wide sense.

$$\frac{h}{m_0 c}=l_{\mathrm{max.}} \quad \text{and} \quad \frac{h}{M_{\mathrm{max.}}}=l_0, \quad . \quad . \quad . \quad (5)$$

where the subscripts max. and 0 denote respectively the maximum and minimum mass or length.

From (3) and (5)

$$\frac{l_u^2}{l_0}=\frac{M_{\mathrm{max.}}\,G}{c^2}, \quad . \quad . \quad .$$

which is also a length.

Comparing this with the well-known equation showing the relation between the mass and the radius of the universe, $\frac{M_u G}{c^2}=\frac{\pi}{2}R$,

we may write

$$\frac{l_u^2}{l_0}=\frac{M_u G}{c^2}=l_{\mathrm{max.}}, \quad . \quad . \quad . \quad . \quad . \quad (6)$$

where $M_{\mathrm{max.}}$ and $l_{\mathrm{max.}}$ are identified with the mass of the universe M_u, and the longest distance in space, $\pi R/2$, respectively.

It is interesting to find the numerical coincidence in the two following cases:

$$\frac{M_u}{m_0}=2A^6 \quad . \quad . \quad . \quad (7); \qquad \frac{M_{\mathrm{H}}}{m_0}=3A^2 \quad . \quad . \quad . \quad (8)$$

M_{H} denotes the mass of a hydrogen atom.

From (7) and (8)

$$\frac{M_u}{M_{\mathrm{H}}}=\tfrac{2}{3}A^4=N=136\times 2^{256}, \quad . \quad . \quad . \quad (9)$$

N being the total number of particles in the universe[2].

From (5), (6) and (7)

$$\frac{l_{\mathrm{max.}}}{l_c}=\sqrt{2}A^2 \quad . \quad . \quad . \quad . \quad . \quad (10)$$

From (2), (3), (6), (9) and (10)

$$\frac{M_{\mathrm{H}}}{m_e}=\frac{3}{\sqrt{2}}\,\frac{ch}{e^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

Furthermore, the Rydberg constant,

$$R_\infty=\frac{2\pi^2 m_e e^4}{ch^3} \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

With any three constants given, we can thus evaluate the rest. Now let us assume the experimental values of c, R_∞ and G, which are comparatively reliable[3].

$$\left.\begin{aligned} c &= (2{\cdot}99774 \pm 0{\cdot}00005)\,10^{10}\ \text{cm./sec.}\\ R_\infty &= (109{,}737{\cdot}42 \pm 0{\cdot}06)\ /\text{cm.}\\ G &= (6{\cdot}658 \pm 0{\cdot}001)10^{-8}\ \text{cm.}^3/\text{gm.sec.}^2\end{aligned}\right\} \quad . \quad . \quad (4)$$

Then we can find the values of h, e, m_e and M_{H} as follows: The value of A is found in (9) to be $6{\cdot}9715\times 10^{19}$, which is an absolutely definite number.

From (1), (4) and (12),

$$h=\left[\frac{c^3}{16\pi^2 R_\infty^2(137)^6 A^2}\right]\frac{1}{G}=\frac{K_1}{G} \quad . \quad . \quad (13)$$

From (1),

$$e^2=\left[\frac{c}{2\pi 137}\right]h=K_2 h \quad . \quad . \quad . \quad . \quad (14)$$

From (4),

$$m_e=\left[\frac{1}{A\sqrt{Gc}}\right]\frac{e^2}{\sqrt{h}}=K_3\frac{e^2}{\sqrt{h}} \quad . \quad . \quad (15)$$

From (1) and (11), $M_{\mathrm{H}}=[3\sqrt{2}\times 137]\,m_e=K_4 M$.

The results agree closely with the experimental values as shown in the accompanying table.

Constant	Calculated value	Observed value[5]
h	$6{\cdot}6213 \times 10^{-27}$ erg. sec. ± 10	$6{\cdot}6189 \pm 36$ $\times 10^{-27}$ erg. sec. $6{\cdot}6242 \pm 10$ $6{\cdot}6133 \pm 34$
e	$4{\cdot}8019 \times 10^{-10}$ E.S.U. ± 7	$4{\cdot}8025 \pm 4$ $\times 10^{-10}$ E.S.U.
m_e	$9{\cdot}099 \times 10^{-28}$ gm. ± 1	$9{\cdot}1070 \pm 14$ $\times 10^{-28}$ gm. $9{\cdot}1073 \pm 24$ $9{\cdot}0171 \pm 14$
M_H	$1{\cdot}6614 \times 10^{-24}$ gm. ± 2	$1{\cdot}6617 \pm 17$ $\times 10^{-24}$ gm.
e/m	$1{\cdot}7605 \times 10^{7}$ E.M.U./gm. ± 2	$1{\cdot}7591 \pm 2$ $\times 10^{7}$ E.M.U./gm.
h/e	$1{\cdot}3788 \times 10^{-17}$ erg. sec./E.S.U. ± 2	$1{\cdot}3761 \pm 6$ $\times 10^{-17}$ erg. sec./E.S.U. $1{\cdot}3782 \pm 7$ $1{\cdot}3773 \pm 1$ $1{\cdot}3771 \pm 7$

Landau Diamagnetism and the Fermi-Dirac Energy Distribution of the Metallic Electrons in Graphite

IT was discovered by Landau[1] that an electron gas should have, besides its spin paramagnetism, an appreciable diamagnetism due to the quantized orbital motions of the electrons in the magnetic field. If the electrons are *free*, the diamagnetic susceptibility per unit volume of the gas, when it is non-degenerate, is given by the Curie law

$$K = -\frac{n\mu^2}{3kT}, \qquad (1)$$

and when it is completely degenerate by the temperature-independent value

$$K = -\frac{n\mu^2}{2kT_0}, \qquad (2)$$

where n is the number of electrons per unit volume, μ is the Bohr magneton, T_0 is the degeneracy temperature defined by

$$kT_0 = \frac{h^2}{2m}\left(\frac{3n}{8\pi}\right)^{2/3}, \qquad (3)$$

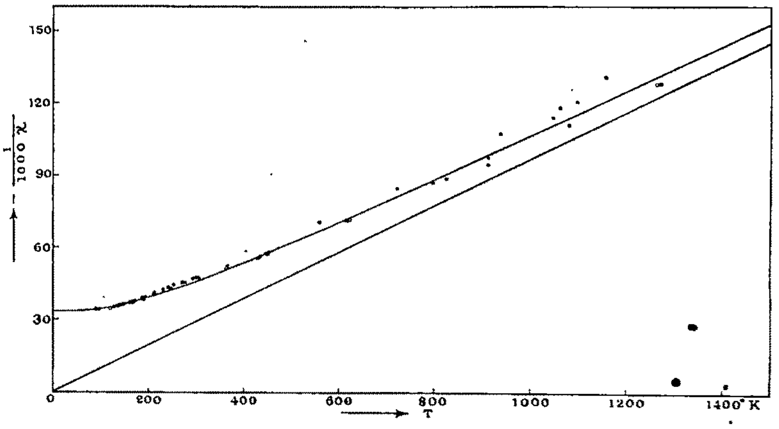
and the other letters have their usual significance. For such a gas the paramagnetic susceptibility is numerically three times the diamagnetic susceptibility and therefore predominates.

For the electrons in any actual metal, which are under the influence of the lattice field, the expressions for the two susceptibilities are naturally more complicated. In particular, the 3 : 1 ratio between them does not hold, and under special conditions the paramagnetic part of the susceptibility may become negligible in comparison with the diamagnetic part. When further, as in graphite, the metallic electrons can move about freely in a plane, and the freedom of movement is confined practically to the plane, the susceptibility along the normal to the plane will conform to equation (1) at high temperatures, and to (2) at low temperatures, the degeneracy temperature T_0 appearing in (2) being, however, much smaller than that given by (3) for electrons that are free to move in all directions.

These results have been verified in graphite. Its abnormal diamagnetism, which is confined to the direction of its hexagonal axis, conforms to equation (1) at high temperatures, and to (2) at low temperatures, with n corresponding to *one electron per carbon atom*, and $T_0 = 520°$ K.; at all temperatures (in the range investigated) the susceptibility per carbon atom is found to be the same as the diamagnetic susceptibility per electron of a Fermi free-electron gas the degeneracy temperature of which is 520° K. The theoretical values for the specific susceptibility (per gram) of graphite, χ, calculated on this basis, are represented by the accompanying curve, and it will be seen that the experimental values, which are denoted by circles, lie close to the curve[2]. The straight line which the curve tends to reach asymptotically at high temperatures is also drawn in the graph, and corresponds to equation (1).

That one electron per carbon atom should be free to move about in the basal plane agrees with the known structure of graphite. There is a Brillouin zone which can just accommodate 3 electrons per atom, which is a flat hexagonal prism bounded by {000,2} and {2$\bar{1}\bar{1}$,0}, and the energy discontinuities across all the faces of the zone are large. There is a bigger zone bounded by {000,2} and {2$\bar{2}$0,0} which can just contain 4 electrons per atom, but the energy discontinuity across {2$\bar{2}$0,0} is small.

The agreement between the experimental data and the theoretical curve plotted in the graph may be regarded as a convincing demonstration of Landau's value for the diamagnetism of a free-electron gas,



and of its temperature variation in accordance with the statistics of Fermi and Dirac.

Total Solar Eclipse of October 1, 1940

THE Joint Permanent Eclipse Committee of the Royal Society and the Royal Astronomical Society has for some years plans prepared for a number of expeditions to observe, what should be a very good eclipse for study, the total eclipse of October 1, 1940. Prof. J. A. Carroll was to have gone from Aberdeen to Brazil with an objective interferometer and an echelon spectrograph for a study of coronal and chromospheric line contours and wave-lengths. The Royal Observatory, Greenwich, and the Cape Observatory were to have gone to Calvinia for a study of the Einstein displacement of stellar images, for a spectrographic study of the chromosphere with a moving-plate camera and for other work. Prof. H. Dingle was to have gone to a station near the edge of the belt of totality for work on wave-lengths and intensities of chromospheric lines near the cusp. The Solar Physics Observatory and the Radcliffe Observatory, Pretoria, were to have joined forces at Nelspoort for a programme including work on the extreme ultra-violet spectrum of the chromosphere and corona, a study of chromospheric line intensities at different heights with a camera having a plate moving intermittently, and polarization studies of the corona and of the sky close to the eclipsed sun.

The outbreak of the War has caused the abandonment of all the expeditions from Great Britain, and the Committee has decided to concentrate on one expedition from the Cape and Radcliffe Observatories to Calvinia. This will carry out as much as proves practicable of the programmes of the various expeditions originally planned. Just how much that will amount to remains to be settled, but every effort will be made to secure as wide a programme of observations as possible.

Cambridge.

Points from Foregoing Letters

A. I. Virtanen and M. Torniainen suggest that the discrepancies in their results and those of others experimenting on the excretion of nitrogen compounds from leguminous roots may be ascribed to the quality of the containers, and especially to their porosity. Observations show that the pots giving best results should be large and very porous.

The effects of alkaline reagents on wool have been reviewed by M. R. Freney and M. Lipson. They find that the sulphur and nitrogen contents of merino wool are scarcely altered by immersion in 52 per cent sodium hydroxide up to 30 minutes; that the surface structure of the fibre is unaltered by similar treatment up to 5–10 minutes; that wool treated with concentrated sodium hydroxide absorbs acid dyes evenly; and that a woven fabric treated with 52 per cent sodium hydroxide solution shows a decrease in shrinkage on washing. These studies were extended to treatment of wools with alkalis dissolved in certain organic solvents.

H. Blaschko describes experiments on the inhibition of amine oxidase by derivatives of β-phenyl-*iso*propylamine; it is shown that there exists a parallelism between the awakening action of these drugs and their inhibitory effects on the enzyme.

A. Polson describes and illustrates an apparatus for studying the mobility of animal viruses and their neutralizing antibodies in an electric field. It is a simplified and less complicated modification of the Tiselius moving boundary method.

Ellen Thomsen finds that maturation of the ovaries in adult female flies is controlled by a hormone produced by the corpus allatum, since extirpation of the corpus allatum of young Calliphora and Lucilia females causes the ovaries to stop development at an early stage, whereas operated controls have fully developed ovaries. The ovaries on the other hand influence the corpus allatum, for removal of the ovaries of young Calliphora causes a considerable enlargement of the corpus allatum.

Lord Rayleigh has been able to detect by an interference method a slight permanent set of a strip of glass exposed for many months to a powerful bending moment.

W. Heitler points out that a number of difficulties (diverging magnetic moment of proton, large scattering cross-section for mesons) are due to an inadequate treatment of the spin and charge. It is suggested that 'higher proton states' with charge $2e$, $-e$, and those with spin 3/2 might exist with a rest mass of 25–50 electron masses higher than that of the proton. The cross-section for the scattering of mesons is then of the right order of magnitude and the magnetic moment of the proton diverges only logarithmically.

According to K. S. Krishnan, the abnormal diamagnetism of graphite along its hexagonal axis is the same as the Landau diamagnetism of the Fermi electron gas containing one electron per carbon atom and having a degeneracy temperature of about 520° K.

RESEARCH ITEMS

Osage Warfare

THE late Francis La Flesche, himself an Omaha Indian and a member of the staff of the Smithsonian Institution, Washington, among his numerous studies of the American Indians, made an elaborate record of the rites and ceremonies observed by the Osage Indians in connexion with the conduct of tribal warfare (*Bull. Bureau American Ethnol.*, No. 101, 1939. Washington, D.C.: Government Printing Office, 35 cents). Before taking any action against an enemy, a council meeting was held to choose a leader. This leader had to fast for seven days, and then three complicated and elaborate ceremonies had to be performed. The rituals making up the Wa-sha-be A-thin or war ceremony comprised twenty-eight separate songs, which, interspersed with processions, ceremonial dances and ancient rites, must be sung at just the right times, in proper order, and by the properly designated singers. The Osage, essentially a peaceful tribe who lived in three separate villages in Oklahoma, had also an elaborate peace ceremony, which was intended not only to promote peace within the tribe, but also with their neighbours. They held the peace ceremony in profound veneration because it was believed that the man who had formulated the rite had received supernatural aid in so doing. Though they were peace-loving, intolerable aggression by a neighbouring tribe would force them to take up arms. At the close of the war ceremony a band of warriors was dispatched to meet the enemy. If victory were achieved the band returned with scalps and prisoners, and victory songs were sung.

Distribution of Ceratium

E. STEEMANN NIELSEN has extended his previous researches (1934) on the Ceratia of the Pacific Ocean ("Die Ceratien des indischen Ozeans und der ostasiatischen Gewässer, mit einer allgemeinen Zusammenfassung über die Verbreitung der Ceratien in den Weltmeeren". Von E. Steemann Nielsen. (Dana-Report No. 17.) Pp. 34. (Copenhagen: C. A. Reitzels Forlag; London: Oxford University Press, 1939.) 3.50 kr.; 3*s*.). It was originally intended to add those of the Atlantic, but as these have been thoroughly dealt with by the two German Expeditions *Meteor* and *Deutschland* (Peters, 1932, and Schubert, 1937) this was considered unnecessary. It is now possible to give a general survey of the distribution of the three oceans and their neighbouring seas. Charts are given showing the distribution of the dominant species in the Indian Ocean and East Asiatic waters and tables of the horizontal and vertical distribution of all of them, with a review of their distribution in the different regions and the numbers in the Nansen net in the stations poor in plankton. The most striking fact that emerges is the homogeneity of distribution and the absence of geographic races or species. As was noted in the southern Pacific, the author regards the two factors temperature and oceanic-neritic influence as of supreme importance in the determination of the distribution of Ceratia. Schubert (1937) regards salinity as of great significance, but the observations of Peters (1932) in the Atlantic and of Nielsen in the Pacific and in the present work are opposed to this. It is agreed that extreme salinity is of importance; but within the limits shown in the open ocean it has apparently little influence on distribution of the Ceratia. The material came almost exclusively from tropical waters. It is found that all Ceratium species which can live in tropical waters are inhabitants of both hemispheres. The cold-water species are, however, only inhabitants of one of them. *Ceratium fusus*, which is well known from both warm and temperate water, inhabits both hemispheres. In the Antarctic there is the cold-water species *Ceratium robustum* inhabiting the whole region, and in the Arctic *Ceratium arcticum*. Most warm-water Ceratia are common to all three oceans, but there are certain forms of purely tropical species found only in the Indian Ocean and Pacific, or only in the Atlantic. This is especially the case with neritic species. The Indian Ocean and the Pacific represent one region so far as the purely tropical Ceratia are concerned.

Offspring from Artificially Activated Ova

S. PINCUS (*Proc. Nat. Acad. Sci.*, 25, 557–559; 1939), following up his previous report that three litters of rabbits had been obtained from recipients of artificially activated ova, shows by further breeding that the transplanted ova which have been activated give rise to normal offspring without fertilization. For example, eighteen chinchilla ova transplanted after activation into an albino doe, which had been made pseudo-pregnant by pituitary extract, gave rise to two chinchilla females, one of which has been further bred by mating to an albino male, giving a second generation of nine chinchilla and three albino.

Seed Weight in the Tomato

THE weight of the seed and embryo in the tomato is dependent on the genotype of the plant, the external environment in which the fruits develop, and also upon certain internal factors such as the number of seeds developing in the fruit and the number of fruits on the truss. L. C. Luckwill (*New Phytol.*, 38, 181–189; 1939) has calculated correlations and regressions between seed weight and these internal factors, and has estimated that variations in seed number may be responsible for variations in mean seed weight as large as 45 per cent. The maximum variation due to differences in the number of fruits developing on the truss was estimated at 10 per cent of the mean. It is suggested that these correlations may arise from causes connected with the nutrition of the developing ovules similar to those which give rise to the negative correlation between birth weight and litter size in certain mammals. These results have a great influence on the design of experiments on heterosis (see also NATURE, Nov. 25, p. 908).

Heterochromatin in the Chromosomes of Drosophila

B. P. KAUFMANN (*Proc. Nat. Acad. Sci.*, 25, 571 577; 1939) has studied the distribution of 627 breaks due to X-rays in the *X*-chromosome of *Drosophila melanogaster*. He shows that there is no difference in frequency or distribution of breaks near or in an inversion as compared with wild-type chromosomes.

There is a significant increase of breaks in certain regions of the chromosome, particularly the known heterochromatin region, and in sections of the euchromatin part. From this and other evidence it is shown that the increased frequency of breaks in the sections of euchromatin is due to the presence of intercalary heterochromatin material.

Interxylary Cork

A PAPER in *Lloydia* (see p. 24 of this issue) by R. A. Diettert upon the morphology of *Artemisia tridentata* directs renewed attention to this interesting phenomenon. When annual growth recommences in the stem in the spring a single layer of meristematic cells, the interxylary phellogen, remains on the surface of the last-formed xylem of the previous year. Quite late in the summer, in July and August, these initials give rise to several layers of cells which suberize progressively in a centrifugal direction. As a result the wood of the current season is carried out on to a wider periphery by this late cork development; the rays are thus expanded and also the cells of the rays, in the region of the cork layer, are suberized progressively in an outwards direction. We thus have the most recently formed layer of wood cut off from all older layers of wood by a sheet of periderm, a process that is repeated in successive years. This must have a most important effect upon the water economy of the plant, which has a wide distribution throughout the western United States. E. H. Moss has directed attention previously to the presence of such rings of cork in herbaceous perennials (NATURE, **133**, 689; 1934), concluding that they afford excellent protection against desiccation and various deleterious effects that might be associated with the dying down of annual shoots.

Softening of Rubber

CRUDE raw rubber as received by manufacturers has to be reduced by heating and mechanical working to a soft plastic condition to permit incorporation of the essential compounding ingredients. Experiments have been carried out by V. H. Wentworth and J. D. Hastings at the Rubber Research Institute of Malaya (*J. Rub. Res. Inst. Malaya*, **9**, Comm. 236 and 237) to determine if softening could not be more economically effected by modifying the preparation of the rubber on the plantation. A promising line of attack is the treatment of latex prior to coagulation with substances such as zinc soaps which bring about softening in the course of the normal smoking and drying processes. Pine tar is an effective softener in common use, and in view of the fact that it was found possible to incorporate large quantities into the latex, it is suggested that master-batch preparation on estates might be worthy of consideration by the manufacturers. The incorporation of emulsions of 'peptizing agents' into the latex in the pre-coagulation stage is another method which has been used during the last two years for softening purposes. It is now shown that the degree of softness achieved depends to a large extent on the temperature at which the wet sheet is afterwards dried, high temperature in the early stages assisting the softening markedly.

Control of Loose Smut Disease

THE original delicate method of controlling the loose smut fungi upon wheat and barley by dipping the seed in hot water for a short period has gradually given place to the more workable treatment of steeping for a longer time at a lower temperature. G. Howard Jones has designed an automatic apparatus for dealing with the seed on cereal improvement farms in Egypt (*Min. Agr. Egypt Tech. and Sci. Service Bull.* 220. Govt. Press, Bulâq, Cairo, 1939. P.T. 3). About 150 lb. of seed contained in a hopper is emptied into a wire basket within a heating bath by means of an automatic electric relay control apparatus which also switches on the heating units. Six hours later, the same apparatus rings an alarm; the wire basket is then hoisted from its bath and the seed spread upon trays to dry in the sun. The heating is accomplished during the night, so that full advantage may be taken of the drying effect of the sun, and thus a continuous series of daily treatments is maintained. Germination is affected to a slight, but commercially insignificant, extent by the process.

The Ogasima (Japan) Earthquake of May 1

THIS is the subject of three papers by T. Hagiwara, N. Miyabe, R. Takei and Y. Otuka (Earthquake Research Institute, Tokyo Imperial University, 17, Part 3, September 1939), who have studied respectively the shock and aftershocks, the deformations of the earth's surface and the geological implications. The earthquake occurred about 14h. 58m. on May 1, 1939, and shocks of the same magnitude followed twice with an interval of two minutes, in the neighbourhood of Ogasima and the neck of a small peninsula in the Akita Prefecture. The aftershocks which followed the main earthquake were observed by four portable seismographs installed temporarily in the peninsula, and these aftershocks were found to have had epicentres near to where the surface effects were greatest within the peninsula, but not all originated in one place. Hundreds of dwelling-houses were destroyed by the earthquake and a landslide which followed it, and 29 people were killed. The surface effects including damage to property, surface cracks and permanent movement were found to be greatest (1) in the neighbourhood of Kitaura-mati on the northern seashore, where also a cliff extending about one kilometre along the Japan Sea slid down to the sea and destroyed more than a hundred houses; (2) near the villages of Anden and Kotogawa where the damage was greatest and surface features most distorted; (3) on the northern slope of Kanpûzan volcano; and (4) in Katanisi-mura, in the narrow isthmus dividing Lake Hatirōgata from the Japan Sea. In several places where the ground was permanently deformed, the horizontal displacements were up to 3·9 m. whilst the vertical displacements ranged about 1 m. Yanosuke Otuka is of the opinion that these displacements were due to surface ground disturbance and that they had no tectonic significance. The landslide however was due to slipping along the bedding plane of the Kitaura sand and mud alternation of the Middle Neogene.

Meteorology of the Byrd Expedition

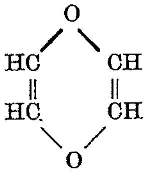
SUPPLEMENT No. 41 of the *Monthly Weather Review* of the U.S. Department of Agriculture, issued last October, is an account running to 377 pages of the meteorological results of the Byrd Antarctic Expeditions of 1928–30 and 1933–35, by C. Grimminger and W. C. Haines. Part of the data had been prepared in the Antarctic in 1929–30 by W. C. Haines and H. T. Harrison. Apart from the introduction, the volume is occupied by the tables in which the meteorological observations are set out. These include the observations made on the various ships of the Expedition between New Zealand and the Bay of Whales, those made at Little America (the base of the Expedition in lat. 78° 34′ S., long. 163° 56′ W., which was at nearly the same spot as "Framheim", where Amundsen obtained 10 months' records in 1911–12) and at the Bolling Advanced Weather Base, which was occupied by Admiral Byrd alone from March 26 to October 11, 1934, and on various sledging journeys. Upper air observations were made with the aid of kites carrying Marvin kite meteorographs. On the first expedition a kite meteorograph was installed on the aeroplane that formed part of the equipment, and on the second expedition an autogyro was taken, primarily for the purpose of making temperature observations, because of difficulties that had been encountered with kites. The best method of mounting the kite meteorograph was found to be that of suspending it within the fuselage to the rear of the cabin on rubber cords, ventilation being secured by having a tube of wind-proof cloth leading from an air vent in the top of the fuselage to the meteorograph. This enabled a perfect record to be obtained on the flight to and from the South Pole. The completeness of the meteorological record under the most trying conditions testifies to the keen work not only of the meteorologists but also of those who assisted, notably the leader of the expedition during his lonely vigil during the whole of an Antarctic winter night less than 10° from the Pole. In spite of difficulties arising from the intense cold, from drifting snow and frosting of the lenses of the pilot balloon theodolites, pilot balloon observations of upper wind were made at Little America on 569 occasions during the 310-day period when the pilot balloon station was in operation on the second expedition. A critical discussion of the results obtained will, it is hoped, be made in due course, although no objection can be made to this early publication of the raw material for such a discussion.

Structures of Ozone and Some Compounds

THE structures of ozone, silicobromoform ($SiHBr_3$) and dichlorogermane (GeH_2Cl_2) contain contributions from several forms among which resonance exists. The dipole moments of these substances have been measured by G. L. Lewis and C. P. Smyth (*J. Amer. Chem. Soc.*, 61, 3063; 1939), ozone being measured in solution in liquid oxygen, silicobromoform in heptane and dichlorogermane in carbon tetrachloride. The moments (in usual units) are O_3, 0·49; $SiHBr_3$, 0·79; GeH_2Cl_2, 2·21. The finite moment of ozone excludes the symmetrical triangular molecule in which each atom is linked to two others by a single bond. A linear molecule with a central atom joined to one on each side by identical bonds is also excluded. A bent structure, analogous to that of sulphur dioxide, seems indicated. The electronic structures which seem likely to the ground state of the molecule are the following: $:\ddot{\mathrm{O}}::\overset{+}{\ddot{\mathrm{O}}}:\overset{-}{\underset{\cdot\cdot}{\ddot{\mathrm{O}}}}:$ $:\overset{-}{\underset{\cdot\cdot}{\ddot{\mathrm{O}}}}:\overset{+}{\ddot{\mathrm{O}}}::\ddot{\mathrm{O}}:$ $:\overset{+}{\ddot{\mathrm{O}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:$ $:\overset{-}{\underset{\cdot\cdot}{\ddot{\mathrm{O}}}}:\underset{\cdot\cdot}{\ddot{\mathrm{O}}}:\overset{+}{\ddot{\mathrm{O}}}:$ and the first two, in which each atom has a complete octet of electrons, should make the largest contribution. All these structures are bent, the O—O—O angle being not less than 120°. It is concluded that the two oxygens linked to the central atom form an angle of about 140° and in any case very obtuse. The two identical bonds have some polar character as a result of resonance among forms containing semi-polar bonds. The results for silicobromoform and dichlorogermane show that silicon compounds tend to have minimum moments in the group of carbon, silicon, germanium and tin compounds, which, otherwise, increase in the order named.

Dioxadiene

THE compound used as the fundamental or parent nucleus for dioxane, dioxene and their derivatives, namely:



previously called dioxin, has now been prepared for the first time by R. K. Summerbell and R. R. Umhoefer (*J. Amer. Chem. Soc.*, 61, 3020; 1939) and called dioxadiene. It was obtained by the action of magnesium and magnesium iodide on 2,3,5,6-tetrachlorodioxane in boiling *n*-butyl ether (no reaction occurred in the lower boiling ethyl ether). Other reactions tried did not succeed. Dioxadiene boils at 75°, which is 26° lower than dioxane, it is insoluble in water, and in its chemical properties it behaves generally as an unsaturated ether. It is, however, more stable towards dilute acid than other unsaturated ethers such as dioxene and vinyl ether. It polymerizes in two to three weeks to a hard colourless solid, not melting below 250°, and insoluble in water, benzene, etc. Dioxadiene reacts vigorously with bromine and adds on hydrogen chloride. The reactions indicate that the unsaturation in the molecule is modified to a marked extent by conjugation with the ether oxygens.

Determination of Meteor Velocity from Zenith Attraction

IN a recent paper, Hideo Inouye shows how meteor velocities can be determined by finding the radiants of a shower at fairly short intervals when the radiant is not far from the meridian (*Mon. Not. Roy. Astro. Soc.*, 99, 9; October 1939). The observations are made when the radiant is near the meridian because the effects of the diurnal aberration in displacing the radiant are then negligible. It is well known that the attraction of the earth on a meteor causes a movement of the radiant towards the zenith, and the amount of this movement depends upon the velocity of the meteor and also on the distance of the radiant from the zenith. From the displacement of the radiant when it is at various altitudes an angle θ can be easily found, and from this latter the value of the velocity is read off from a table. An example is given from the Leonid shower of November 13, 1937, and from this the velocity of the meteors associated with this shower is 59·5 km./sec. The actual value is 71·4 km./sec., and it is suggested that this can be explained by errors of observation in the amount of the displacement. Although the method is interesting, it does not lend itself to very high accuracy.

COPROPHAGY IN THE RABBIT

By DR. A. EDEN,

VETERINARY LABORATORY, MINISTRY OF AGRICULTURE AND FISHERIES, WEYBRIDGE

COPROPHAGY in the rabbit was discussed in NATURE (1939) under the title "Does the Rabbit Chew the Cud ?" and the early observations of Morot (1882)[1] were confirmed by Madsen[2] and by Taylor[3]. These observations showed that two kinds of fæces were voided by the rabbit, the familiar dry pellet type during the day and a soft mucous type during the night, rarely observed because the animal collects them directly from the anus and swallows them again. Madsen suggested that the difference in the two types was due to an intestinal rhythm in the rabbit itself and that refection was a normal physiological process in this animal. Taylor, on the evidence of coccidial oocysts found in the stomach and of experimental feeding with lycopodium spores, agreed with Madsen and emphasized the necessity for recognition of this peculiar attribute of the rabbit in the correct interpretation of parasitological and physiological work in which this animal is employed. In the latter connexion he cited specific experiments of mine on the fate of ingested copper, some of the data of which may be more fully discussed.

In one of the earlier experiments it was observed that the elimination of 50 mgm. of copper (as the sulphate, dried on to food) was spread over five weeks: 22·5 mgm. appearing in the first week, 14 mgm. in the second, 6·4 mgm. in the third, 2·4 mgm. in the fourth and 1·3 mgm. in the fifth week, the remaining 3·4 mgm. being probably accounted for by summation of analytical error over some 35 analyses. Other evidence was available that the retention of such large quantities of copper could not be due to absorption from the alimentary tract and storage within the body with subsequent elimination, and the only rational explanation seemed to be refection of the copper-containing fæces. Since, however, half the quantity of copper finally accounted for was still present in the tract after a week, calculation shows that 80–90 per cent of the total fæces excreted must have been re-eaten, according to the interval assumed for complete passage of food through the tract, or 4–9 times the amount which actually passed through the wire-mesh floor of the cage. Such a high degree of refection seemed incredible even with an animal receiving a quantity of food well below its maximum appetite level.

On repeating this experiment, killing the animal after a week and analysing the contents of the tract, the tract itself as well as the major tissues, 38 mgm. of the copper fed were found to have appeared in the fæces during the week as against 22·5 mgm. in the previous experiment and a further 12 mgm. were found in the contents of the tract (2·5 mgm. in stomach, 1 mgm. in the intestines, 5 mgm. in the cæcum and 3·5 mgm. in the rectum) while the wall of the tract itself and the tissues contained only the usual 0·2–0·5 mgm. per cent fresh material. The high amount of copper found in the stomach contents afforded particularly strong evidence of refection, and calculation from the observed excretion of copper suggested reconsumption of 50–70 per cent of each day's rectal deliveries.

Another experiment with a rabbit provided with a wooden collar, presumed large enough to prevent the animal getting at its anus, was undertaken, and the dry matter and copper fæcal excretion studied. In a five days preliminary uncollared period, an average daily excretion of 9·5 gm. dry matter was observed, of the ordinary familiar pellet type. After attaching the collar, 54·5 gm. dry matter appeared within twenty-four hours, 37·5 gm. being present in the normal 'day' fæces and 17 gm. in the softer 'night' fæces type, consisting of mucous covered agglomerates of much smaller pellets suggestive of loganberries. On the assumption that 9·5 gm. dry matter would also have been obtained on the sixth day but for the collar, the actual appearance of 54·5 gm. suggests that 45 gm. would have been eaten had the animal been able to get at its anus, a calculated 'refection level' of 82 per cent of the total excretion. This is astonishingly high and may perhaps have been accentuated by irregularity of rectal evacuation although there is no reason for such an assumption.

50 mgm. of copper had again been incorporated with the food the day the collar was attached and 96 per cent was recovered in four days: 10 mgm. on the first day, 25·5 mgm. on the second; 6·9 mgm. and 5·7 mgm. on the third and fourth days respectively; the remaining 4 per cent appeared over the next few days. This presumably represents the ordinary rate of passage through the tract, the lag over the third and fourth days probably being explained by the large storage capacity of the cæcum, and is in striking contrast to the behaviour noted in rabbits allowed to practise their customary coprophagy.

Excluding the first day of high fæcal excretion after collaring, the average dry matter over the next fifteen days was 13·7 gm. daily, 4·2 gm. more than in the five uncollared days on the same ration. This at least suggests that refection increases the extent of digestion of the dry matter of the food, and taking the daily dry matter intake as 37 gm., digestion coefficients for the collared period were 63 per cent, and for the uncollared period 77 per cent when the material was passed through the tract several times. As showing the extent of the craving for fæces, after twelve days the rabbit discovered a cunning method of circumventing the collar and was able to secure occasional pellets from the anus although often rolling over in the process.

On replacing the collar by a larger one and again feeding 50 mgm. copper a few days later, 6·5 mgm. appeared within twenty-four hours. The collar was then removed. Less than 4·5 gm. dry matter appeared over the next twenty-four hours and copper recovery diminished although the output of fæcal matter again rose and a further 36·5 mgm. copper were recovered in the ensuing seven days. On again replacing the collar practically all the remaining copper appeared in two days, during the first of which the fæcal dry matter rose from 13 gm. to 28 gm. with the reappearance of 'night' fæces. Again on the assumption that the actual rectal output was the same as on preceding days, the drop of fæcal dry matter actually collected, 13·7 gm. to 4·5 gm., represents a refection of 9·2 gm. or 67 per cent of the total passing the anus. Similarly when the collar was next replaced the rise in fæcal dry matter from 13 gm. to 28 gm. represents a minimum refection of 15 gm. or 54 per cent—the real figure being higher if one assumes a tendency to greater retention in the tract when refection is suddenly prohibited.

Naturally the degree of refection varies with each individual rabbit, with the amount of food, probably with the chemical composition of the food and with disturbance of habit by intermittent collaring. In the last mentioned experiment the refection level apparently varied from 54 to 82 per cent at different periods, and in the first experiment, in which elimination of copper was spread over five weeks, the average daily refection must have exceeded 80 per cent of the total fæces passing the anus.

A further point of interest is the difference in ash content, on a dry matter basis, between 'day' and 'night' fæces on the particular diet employed: 6·5–10 per cent in the 'day' fæces and 11·7–14·5 per cent in the 'night' fæces. Further investigations are in progress regarding other differences in chemical composition and on the relation between time of feeding and the appearance of pellet types.

CHARITY AND THE STRUGGLE FOR EXISTENCE*

T. H. HUXLEY in his famous Romanes Lecture startled the University of Oxford by saying, or seeming to say, that the cosmic process as represented by the struggle for existence "works not for righteousness but against it". Apparently his contention was that the use of tooth and claw was to be contrasted with the more civilized methods of maintaining the race in being. Huxley, however, did not define the precise function to be attributed to the higher morality as a means of survival. It remains, therefore, for the anthropologist to inquire what actual evidence there is for the view that what is salvation for the brute, or even for the savage, spells damnation for a reasonable being knowing good from evil.

"Real progress is progress in charity, all other advances being secondary thereto"[1]. Huxley himself would have been the first to insist that what he terms ethical process involves 'charity' as a typical manifestation of pure goodness. If 'charity' then be taken as a mark of the spiritual man, how far does a disposition towards it set him at variance with his former self, the natural man?

Now, on the plane of anthropology, Dr. Marett disclaims at once any intention of trying to determine more than the biological function of morality, and in particular that of charity as its crowning grace. This method can at least furnish an external criterion of their worth. On a long view, such as that taken by the anthropologist, it becomes plain that certain types of conduct are of greater biological advantage than others—that they promote the survival of those who live accordingly. Further, they have the advantage that the anthropologist, who must with his evolutionary outlook insist on continuity at all costs, can recognize in man a steadily increasing purpose to make the best of his life, and he cannot but treat primitive and advanced morality as lineally related expressions of the same basic motive.

Charity would seem to be rooted in mother-love, on which the protracted infancy of our species makes it specially dependent; for they both involve a like readiness to give regardless of desert and with no thought of a return. At the same time, having regard to certain tendencies in human nature in virtue of its bi-sexual constitution, justice may be linked with fatherhood, while a certain virtue which may be roughly identified with holiness represents the effort to transcend the psychological opposition between them.

Justice then may be regarded as the outcome of male masterfulness, which in course of time establishes a system of rights and duties having strict reciprocity as its ideal limit. Father-right, however, has prevailed over mother-right in the evolution of the greater society, so that modern civilization is threatened with a type of authoritarian State given over to a harsh legalism insufficiently tempered by mercy. That so one-sided an exploitation of man's spiritual resources is unhealthy is possibly illustrated by the fact that the world's successive civilizations, all alike built up on power politics, hitherto have invariably come to grief.

Family life, however, outlasts the decay of nations; and for the anthropologist, it is suggested, the key to the understanding of human development on its moral side is not so much the evolution of the State as that of the family. In no department of life has experiment played a greater part, though only on the cultural side is this possible, since the biological conditions are virtually fixed. It might even be argued that the whole social process is fundamentally an attempt to resolve the temperamental conflict of sex into a harmony sufficient to ensure the continuation of the species.

Here then in family life lies the best hope of striking a balance between gentleness and firmness in human intercourse.

As for what has here been called holiness, the history of religion shows that there have always been high-minded persons who tended to turn away from sex as too disturbing a factor in the moral life. But to starve by way of sublimating sex can at best be but an indirect way of promoting the survival of the race. It must be left rather to ordinary men and women to make their characteristic but diverse contributions to a morality which will ever consist in a compromise between discipline and love. Such is the two-fold aim of that traditional nurture which has become man's second nature and alone can bring him safely through the ages that lie ahead.

---

SOME INDIAN ORIGINS IN THE LIGHT OF ASTRONOMICAL EVIDENCE

AMONG recent communications to the Royal Asiatic Society of Bengal, several dealing with details of a technical character in palæographical and historical studies bear upon points of interest and importance in the archæological investigation of the origin and development of Indian civilization*.

In a discussion by S. N. Chakravarti of the development of the Bengali alphabet from the fifth century A.D. to the end of Mohammedan rule, in which the argument depends upon a detailed examination of variations in form, the Bengali alphabet is derived from a proto-Bengali of the tenth century, which in turn it is suggested can be traced back to certain ancient prototypes in the pictographic script of the Indus Valley civilization. It is also suggested that the Indian system of notation, for which affinity with Egyptian demotic has been indicated, is in reality indigenous in origin, probably to be traced back to the seals of the Indus Valley.

Conclusions of a more surprising character, based on astronomical evidence, have been formulated by P. C. Sengupta in a series of papers discussing chronological and other problems in early Indian history. The first of these deals with the date of the Bhārata battle, the great conflict which forms the central incident of that great monument of early Indian literature, the Mahabharata. The date for this battle, as usually accounted, is indicated by three lines of traditional evidence at 3102–3101 B.C. The author, on an examination of one of these traditions, the evidence of the Yudhiṣṭhira era, has shown that the astronomical references justify the inference that the great battle took place in 2449 B.C. He now turns to examine the remaining two traditions, the Āryabhaṭa and the Purāṇic traditions.

The calculation depends upon the dating of the Kaliyuga, which the Mahabharata states had just begun and to which the date February 3102 B.C. is assigned. It cannot, however, be reconciled with the astronomical Kaliyuga, and is shown to be based upon an astronomical calculation in which conditions are correct only for A.D. 499, when the Hindu scientific Siddhantas came into being. It depends upon an incorrect assumption of the position of the solstices of Pandava times and an incorrect annual rate of the precession of the equinoxes. A corrected back calculation from conditions in the heavens corresponding to those recorded in the Mahabharata, that is, conditions in the period February 1924–35, gives a date January 10, 2454 B.C. as the beginning of this Kaliyuga era, and 2449 B.C. as the year of the battle.

This leads to further inquiry as to observation of the solstices in successive ages. This was determined by the phases of the moon in the month of Māgha, a lunar month of which the beginning at the present time may be from January 15 to February 11. In the calendar of the Vedic Hindus, this month started the five-year cycle which began "when the sun, the moon and the Dhaniṣṭhās (Delphinis) cross the heavens together; it is the beginning of the Yuga, of the month of Māgha or Tapas, of the light half and of the sun's northerly course". From the astronomical conjunctions to which reference is made in the Mahabharata, it would appear that this reckoning was started (traditionally by Brahma) at about 3050 B.C.

There are three peculiarities of this month: (1) it began with a new moon near Delphinis; (2) the full moon was near Regulus; (3) the last quarter was conjoined with Antares. Such a month did not come every year, but it was the standard month of Māgha. In our own times it occurred in 1924 during February 5–March 5, a year which for the purpose of this investigation is taken as the gauge year.

References in the Brahmanic and other works directly state or indicate the winter solstice of successive Vedic periods. From these astronomical references fixing the position of the moon in relation to the winter solstice and the beginning of the month Māgha, a matter of ritual importance in connexion with the year-long and other sacrifices, it has been possible to fix by calculation back from the corresponding conditions in recent years a series of dates beginning with 3550 B.C., the earliest date of the age of the Brahmanas, and covering a period of 1,450 years with a possible error of 400 years. It was thus during this period that the Brahmanic literature developed.

Next is considered Madhu-Vidyā, or the "science of Spring" which as here interpreted is really the knowledge of the celestial signal for the coming of spring, addressed to the Aśvins, who are identified with α and β Arietis, the prominent stars in the Aśvini cluster. The three stars, α, β and γ Arietis, form a constellation which is likened to the head of a horse. The Aśvins are spoken of in several passages of the Rig-Veda as riding in the heavens in their triangular, three-wheeled, and spring-bearing chariot.

From certain references it would seem that when the car of the Aśvins first becomes visible at dawn, spring began at some place in the latitude of Kurukṣetra in the Punjab. The jealously guarded Madhu-Vidyā or "science of Spring" was thus nothing but knowledge of the celestial signal of the advent of spring—the heliacal rising of α, β and γ Arietis.

By astronomical calculation it can be shown that this event at the latitude mentioned took place at, say, 4000 B.C. Hence it is beyond question that the Vedic Hindus could find accurately the beginnings of winter, spring and all seasons of the year.

The earliest epigraphic evidence of Vedic chronology from cuneiform inscriptions referring to Indra and other gods of the horse-riding Kharri or Mitanni dates from about 1400 B.C. In the absence of further epigraphic evidence, it is pointed out, this definite finding of the astronomical evidence derived from the literature as to the antiquity and chronology of the Vedas must be allowed to stand. It establishes, it is maintained, that the civilization of the Vedic Hindus was earlier than that of the Indus Valley as evidenced by the remains at Mohenjo-daro.

Finally, in "When Indra became Maghavan", Mr. Sengupta turns to the relation of the Vedic god Indra, the "shedder of rain" and "the wielder of the thunderbolt" to the summer solstice. The references to this god in the Rig-Veda, when divested of all allegory, suggest that he is the god of the summer solstice, while the clouds as represented by a demon are unwilling to yield up their watery store until assailed by the thunderbolt hurled by the god.

---

* See *J. R. Asiat. Soc. Bengal, Letters*, 4, 3 (1938); issued September 1939.

The monsoons which bring the rains usually burst about June 22 and there is usually a drought which lasts for about a month before the monsoon comes. The demon Suṣṇa (drought) is killed by Indra. The fight with Vrtra or Ahi, the cloud demon, is thus an annual affair which takes place when the sun enters the summer solstice, Indra withdrawing his rain-giving (or annual) bow with the coming of autumn.

When did Indra become the slayer of Vrtra ? The answer given by the Rig-Veda is when Indra by the rising of Maghas became Maghavan. Maghas to us must be the constellation Maghās consisting of α, η, γ, ζ, μ and ς Leonis, at the heliacal rising of which the sun reached the summer solstice at the latitude of Kuruksetra (lat. 30° N.). This it is shown must have happened in 4170 B.C.

APPLICATIONS OF PHOTOGRAPHY TO ENGINEERING

IN a paper delivered to the Junior Institution of Engineers on November 4 and published in the journal of the Institution for December, Mr. A. H. Styring gives an account of several practical applications of photography to engineering. He lays special stress on infra-red photography, photography by polarized light, X-ray photography and high-speed photography.

Infra-red sensitive materials have proved of the greatest value in spectroscopy and astronomy. Photographs of the solar spectrum have revealed lines as far as 13,500 A. wave-length. Distance appears hazy on non-colour sensitive materials because the suspended particles of water vapour in the atmosphere, which are transparent and therefore affect vision only slightly, act as a thick medium for deep violet and ultra-violet waves, scattering them, and producing an effect similar to that which would be seen if we were to try to look through a sheet of finely ground glass.

When photographing at great distances, the best results are obtained with infra-red sensitive materials and filters. Infra-red waves are less easily scattered by water and dust particles in the intervening atmosphere than are the shorter rays in the normal visibility range. The power of haze penetration is important and has an engineering application. Research is in progress for the adaptation of infra-red sensitive materials for navigational purposes. Good work has been done up to six miles, and distances up to twenty miles have been claimed. Special infra-red cameras have been fitted to trans-Atlantic liners in which infra-red film is exposed at 20-second intervals, each picture being developed and fixed rapidly for viewing in roughly one minute. In the same way application has also been made for military purposes, permitting vision of objects invisible to the eye. Other applications depend mainly on the fact that many dyes and pigments, which absorb strongly in the visible region, either transmit or reflect freely in the near infra-red region. In consequence it is possible to reveal by infra-red photography many structures invisible to the eye, and to differentiate between materials which to the eye appear similar. This has a useful application in photomicrography. Another promising field lies in the direction of research in the realm of elevated temperatures. Heat rays are recorded by infra-red materials.

Polarized light photography is based on the fact that light reflected from a non-metallic surface at an angle of 32–37° is strongly polarized. At other angles except 90° it is to variable extents. For this reason the reflection from natural things, separately and combined, has much of the light polarized. The unaided eye fails to detect this, but many objects viewed by a polarizing screen assume a new and strange beauty. The use of polarized light in photography is made possible by the way in which all natural substances reflect polarized light. When a ray of light falls on a sheet of paper, for example, the light that is reflected is composed of two parts, which are called 'specular' and 'diffused' components. The specular component produces 'gloss' and enables us to see more or less distinctly an image of the source of light. If we look at our object through a polarizing screen, we find that we can orient the screen so that practically all the specular reflection is stopped and we see the object by diffusely reflected light. Polarizing screens have recently been made from a quinine-iodine compound called 'Herapathite', a thin layer of the substance being cemented between two sheets of plane glass. The use of such a screen permits photographs to be taken obliquely through water or glass.

The principal application of X-rays to industry is the examination of articles during manufacture. Increased penetration is constantly being achieved and the definition of radiographs has been greatly improved. It does not necessitate expensive castings or forgings being either sawn asunder or otherwise destroyed or mutilated. With a little experience, defects such as gas cavities, sand and slag inclusions, metal segregation, etc., can be easily detected. The atomic weight of the substance examined has a marked effect on the depth of penetration of the rays. Apart from this fact, penetration depends on the voltage applied to the tube. For example, 40,000 volts will penetrate 4 in. of aluminium, but it requires 250,000 volts to penetrate 4 in. of steel. The gamma radiations of radioactive substances have latterly been employed for the same purposes as X-rays. Owing to their shorter wave-length the gamma rays have a much greater penetrative power.

The author points out that with high-speed photography, the ordinary type of motion camera which has an intermittent film motion and shutter can only be speeded up to ten times its normal speed before rupture takes place. Cameras operating at higher speeds have continuously moving films. In the mechanism of the high-speed camera perfected by the Western Electric Co. and Kodak Ltd. there is incorporated a clock, and this records the exact time when each event in a cycle takes place.

FLUID FILLING-MEDIA FOR ELECTRICAL APPARATUS

THIS paper, written by F. Meyer of the General Electric Co., was allocated for reading to the Institute of Electrical Engineers on November 23 and is now published. The author discusses the everyday fluid insulators used for electrical apparatus, particularly with transformers, and advances suggestions for improving the British Standard Specification (148, 1933, Insulating Oils for Electrical Purposes). In addition he discusses the properties of chlorinated diphenyls, perhaps the commonest non-inflammable liquids used for this purpose, which are known in America under the technical name 'pyranol'. The particular requirements of oils suitable for condensers are also considered.

When oil was first adopted for filling transformers and switchgear, use was made of the best existing kind of oil. Going back no farther than thirty years ago, we find that oils were fully approved that would now be instantly rejected, both with regard to their electrical properties and their other physical characteristics. In successive editions of the British Standard Specification 148, the requirements have been tightened up until the oil which satisfies Spec. 148 could be safely used medicinally. Unfortunately the demand of the transformer manufacturers was for an oil based on its sludge value and tested by a method far removed from service conditions, and very little attention was paid to its other properties. It is a well-known fact that the oxidation products of an oil at 150° C. are very different from those taken at 90° C. both in quantity and character. As a test for the eradication of unsuitable oils the author thinks that the Michie test has outgrown its original use.

Fifty per cent of the transformer oil used to-day is Grade *A* oil, typical examples of which give practically zero sludge values. For switchgear purposes where sludge is of small importance, highly refined oil is quite unnecessary. The less refined also the oil the cheaper it is, a point of importance when we consider the large bulk of oil used. Class *B* oils, which formerly were just obtainable with sludge values between 0·7 and 0·8, are to-day readily procurable at the low figure of 0·3 or even less. The author points out that in bringing the sludge value of oils down to these low limits the danger of the development of acidity is now as menacing as the old danger of high sludge values was. It may well be that in the light of modern experience, the highly refined *A* oils employed so widely to-day which have practically zero sludge value will be discarded and an oil of a moderate degree of refinement, but low developed acidity, will become the standard of transformer oil. Tests of *A* and *B* oils taken over a period of six months show that the rate of acidity increases for both oils, for the first three months is much the same but for the next three months the average acidity of the *A* oil increases much more rapidly than the *B* oil.

The greatest drawback of oil as a filling medium is its inflammability. In consequence of recent disastrous fires at Bradford and Kingston due to the oil in transformers and switchgear, and also the danger of fire from incendiary bombs, engineers have been recently studying closely the only non-inflammable liquids at present available, that is, synthetic chlorinated compounds. The commonest of these are the chlorinated diphenyls made in America and on the Continent but not yet manufactured in Great Britain. The degree of inflammability of pure chlorinated diphenyl, generally called in Great Britain 'aroclor', depends on the degree of chlorination. Experiments demonstrate not only the non-inflammability of 48 per cent chlorinated aroclor but also that, in addition, it has the valuable property of acting as a fire extinguisher.

In conclusion, the author discusses condenser oils, which are generally pure mineral hydrocarbon oils. Service conditions in this case are so severe that they cannot be used as delivered by the oil refiners, which can safely be done with transformers.

ROAD SURFACE TEXTURE PRINTS

THAT surface texture is an important factor in determining the resistance of a road to skidding has long been recognized, and at the Road Research Station one of the studies which has received attention has been the development of a satisfactory method of recording this quality. The latest device is an adaptation of the method of offset printing, and it is also the simplest and the most revealing in that it readily lends itself to a study of the changes which occur during the life of the road carpet and of its progress towards failure. A few square inches of the road under examination are cleaned of dust and then carefully inked over either by an ordinary half-tone black printing ink diluted with paraffin or by a water letterpress ink. A clean rubber roller, of specified hardness, is then run over the inked area and the impression taken by the roller is transferred to a sheet of white paper.

The prints which are obtained in this way are remarkable for the wealth of detail which they exhibit, even the finest particles on the surface, about a thousandth of an inch in diameter, being recorded. A Bulletin—Road Research Bulletin No. 3 ("A Printing Method of Recording Road Surface Texture". H.M. Stationery Office. 9*d*.)—just issued by the Department of Scientific and Industrial Research and the Ministry of Transport; gives a description of the process and of the apparatus which, it may be mentioned, packs into a suit-case. It exhibits a number of reproductions of prints taken by the process and these show the stones in the road surface appearing as in relief, the shading of the ink giving a stereoscopic effect. The interpretation of the prints requires experience, and though a surface likely to be slippery is easily recognizable, the assessment of the relative slipperiness of various carpets from their texture prints is more difficult. A series of these prints exhibits the changing nature of a given road surface; the prints are very convenient both for comparison and for storage.

PLANKTON OF THE JAVA SEA*

AN interesting preliminary investigation into the plankton of the Java Sea by Dr. H. C. Delsman shows that the coastal waters contain much plant and animal life and that towards the central part larger animals abound. The two monsoons, the east monsoon about September and the west monsoon about February, have an important influence on the currents.

Two special cruises were made across the Java Sea, from Java to Borneo and from Borneo to Java, when a number of stations were made. The first cruise was in April at the end of the wet, west monsoon, the second in October at the end of the dry, east monsoon. Vertical hauls were also made from near the surface to near the bottom. A comparison of the catches shows that the volume of plankton is higher in October, even if it is taken into account that at this time the larger organisms predominated, such as salps, siphonophores and mysid and amphipod crustaceans. The diatom plankton was generally found along the coasts, whereas the zooplankton was greater farther out and in the middle of the Java Sea, where diatoms were practically absent but where, sometimes, there were masses of Trichodesmium. The coastal plankton is generally of a finer composition, and besides diatoms contains numbers of the smaller copepods. Copepods, both small and large, abound and are the main food of the plankton-eating fishes.

The largest and commonest copepod is *Undinula vulgaris*, reaching in the female 3 mm. in length. This species is absent near the coast at both seasons and is found at a maximum away from the coast but is not present in the middle of the Java Sea. In April it appears in greater numbers than in October. Fishes sometimes have their stomachs full of Undinula, which in value as fish food may be compared with *Calanus finmarchicus* in other seas. *Labidocera acuta*, another large copepod, apparently occurs under more oceanic conditions, occasionally replacing Undinula. The presence of the larger species of copepods at a certain distance from the coast is of much importance in connexion with the fisheries, and further studies in this direction should be of great value. This part of the sea is already a favourite place for the mayang fishers to put out their nets for carangids and clupeoids, presumably where their copepod food is most abundant.

It is found also that the structure of the gill rakers of the plankton-eating fishes, their shape and the nature of the eyes are different in the different regions. Those clupeoids which feed in the coastal waters on the fine plankton have finer and more numerous gill rakers; those feeding a certain distance from the coast, where the plankton is much coarser and probably swallowed more discriminately, have much coarser gill rakes, a more slender body and larger eyes, thus being more capable of darting after their prey. The higher the number of gill rakes the greater their length and the smaller the diameter of the eye.

It is to be hoped that these preliminary plankton studies will lead to others on a larger scale.

SEVENTY YEARS AGO

NATURE, vol. 1, January 6, 1870

Plea for the Mathematician

PROF. J. J. SYLVESTER, F.R.S., in an article based on his presidential address at Exeter to the Mathematical and Physical Section of the British Association said: "Some people have been found to regard all mathematics, after the 47th proposition of Euclid, as a sort of morbid secretion, to be compared only with the pearl said to be generated in the diseased oyster, or, as I have heard it described, 'une excroissance maladive de l'esprit humain'. Others find its justification, its 'raison d'être', in its being either the torch-bearer leading the way, or the handmaiden holding up the train of Physical Science. . . . What is it to us, they say, if the three angles of a triangle are equal to two right angles, or if every even number is, or may be, the sum of two primes, or if every equation of an odd degree must have a real root ? How dull, stale, flat and unprofitable are such and such like announcements ! . . . But this is like judging of architecture from being shown some of the bricks and mortar, or even a quarried stone of a public building—or of a painting from the colours mixed on the palette, or of music by listening to the thin and screechy sounds produced by a bow passed haphazard over the strings of a violin."

Force of the Human Heart

IN an article on "The Labouring Force of the Human Heart", the Rev. Prof. Haughton, F.R.S., states that "its energy equals one-third of the total daily force of all the muscles of a strong man; it exceeds by one-third the labour of the muscles in a boat-race, estimated by equal weights of muscle, and it is twenty times the force of the muscles used in climbing, and eight times the force of the most powerful engine invented as yet by the art of man.

"No reflecting mind can avoid recognising in its perfection, and regarding with reverential awe, the Divine skill that has constructed it."

A SUCCESSFUL treatment for snake bite is recorded from the Rio Grande. Two horses were bitten by the same rattlesnake. A few hours afterwards the submaxillary, parotid, and all glands situated about the head and neck were greatly enlarged; from the nostrils and gums, a clear mucous discharge ran down; the eyes were glairy, with the pupils greatly dilated, and the coat was rough and staring. To each animal Dr. Bell gave half-a-pint of whisky, with a little water, and half an ounce of ammonia, while the wounds were fomented with a strong infusion of tobacco, and afterwards poulticed with chopped tobacco leaves. Both horses recovered.

"In furtherance of natural science work at Eton, an excellent telescope has been recently given to the school by the energy and liberality of some of the masters." Mr. H. G. Madan describes the instrument, a refractor of 5·9 in. clear aperture and 88 in. focus, made and erected by Messrs. Cooke and Sons, of York; it was equipped with a battery of eyepieces, of powers ranging from 30 to 400, and with a bifilar micrometer.

THE trigonometrical survey of England and Wales, on the scale of one inch to a mile, has been completed during the past week. It was commenced in the year 1791.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in the Electrical Engineering Department—S. C. Laws, Northampton Polytechnic, St. John Street, E.C.1 (January 8).

A Director of Studies for British Institute, Rome—The British Council, 3 Hanover Street, W.1 (quoting 'Italy') (January 13).

Civilian Surveyors of Works for the Military Engineer Services, India—The Military Department, India Office, S.W.1 (marked 'Surveyors Recruitment') (January 15).

Assistant Headmaster (later to become Headmaster) for the Mackay School, Valparaiso, Chile—The British Council. 3 Hanover Street, W.1 (quoting 'Chile') (January 20).

Temporary Forecasters, Grade II (Male) in the Meteorological Office—The Under-Secretary of State, S.2.B (Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

UTILIZATION OF SCIENTIFIC MAN-POWER

THE concern which has recently found expression as to the position of science in the war effort of Great Britain, and the extent to which the services of scientific workers are being utilized, is evidence that the importance of this contribution is recognized far beyond the ranks of scientific workers themselves. The apparent tardiness with which the maximum contribution of science is being developed in the war-time effort of Great Britain has caused much questioning, and it is to be hoped that the activities of the newly appointed Advisory Council on Scientific Research and Technical Development will quickly overcome at least some of the obstacles which have appeared.

Political and Economic Planning (P E P) published a year ago an admirable broadsheet on "Man-Power Policy" in which four principles were laid down as essential and suggestions made for giving effect to them. It has now published a review of the present situation and its relation to economic policy under the title "Industrial Man-Power", in which the effect of expansion and contraction in industry in war-time is considered. The table showing the changes which have occurred in certain industries between 1923 and 1938 in Great Britain and Northern Ireland suggests that the great 'dilution' problem of the War of 1914–18 may be of much less importance to-day, since there now exists a range of metal trades already staffed for munitions, without the need to create them afresh.

This factor particularly affects the position of women, and it is accordingly unlikely, in view of the work already carried out under the Industrial Health Research Board and the National Institute of Industrial Psychology, that the grave social problems arising out of physical difficulties through the industrial employment of women will recur. The chief reason for alarm indeed appears to lie in the tendency of the Government to dispense with the Factories Act. The recent report of the Industrial Health Research Board recalls that its work was born of the experience of the War of 1914–18, but there are signs that scientific workers must bestir themselves if that entirely new attitude towards the study of working conditions and industrial welfare is to be preserved under the stress of the present war.

In industry as in civil defence, there is already evidence that the over-working of men and women has begun, and there are no signs of a consistent and well-understood policy in granting permission to work overtime. Equally it is important to conserve our limited resources of skilled labour by training, on a sufficient scale, fresh recruits for the less skilled operations. A scientific policy, which will keep alive the protective machinery and handle such problems before they become serious enough to damage health and efficiency, demands the co-operation of scientific workers as much as the prosecution of fresh research in these fields.

The difficulties experienced at the moment, however, are chiefly of a special and local character. There is some difficulty in spreading the available skilled workers evenly over the field, especially among the new munitions and aircraft factories. Social difficulties also attend the provision of the non-factory groups with work in munition factories. The dangers and opportunities in bringing many of these unorganized workers into official organizations are immense. Again, the labour requirements of several large industries, such as the textile groups, depend very much on policy, particularly export policy, and for this reason lack of a clear economic policy on the part of the Government is being held responsible for the rise in unemployment.

The P E P broadsheet forecasts a considerable scarcity of male labour in the coal-mining, shipbuilding and other heavy industries, rather than in the munitions industries, and stresses the fundamental changes in the whole structure of British society since the War of 1914-18 in relation to the industrial sources of man-power for the forces. A much greater proportion of the population is engaged in selling goods or performing personal services, and the entire non-factory working-class is larger in relation to the rest of the population. Of the non-factory groups, a much larger proportion are now employees rather than employers or workers on their own account. The distributive trades, personal services, and other non-factory trades and occupations are regarded as important sources of personnel for the fighting services and civil defence.

The change in the framework of labour relations involves, for a thorough study of the man-power problem, a survey of the changes in organization, and the broadsheet comments on the great "civil service" which has grown up in industry, represented by thousands of paid officials, hundreds of joint committees and slow-moving democratic machinery. Smooth adaptation of labour relations to war problems as they arise will depend on whether such constitutions reveal latent elasticity or become too brittle to bear the strain.

The value of the National Register as a basis for the scientific use of man-power does not require stressing here. The P E P broadsheet refers particularly to the Central Register of scientific, technical, professional or higher administrative workers, which is already being used by Government Departments and by firms engaged on work of national importance. Much unemployment still exists, however, among highly trained technical workers, particularly graduates in chemistry and other sciences, and even among professional workers such as architects, whose services would be expected to be in demand in numerous problems involved in civil defence and evacuation. A special section of the Central Register has been formed of those in this position, but the preservation of their abilities would seem to require a considerable extension of research programmes, even if such activity has no immediate connexion with war. So far as chemists are concerned, the establishment by the Chemical Society of an Advisory Research Council already provides a means for pooling suggestions for research and bringing them before those engaged in research in the universities and colleges.

Something more is required than improvements in placing methods. Formulation of a really adequate programme of work and its adoption by the Government could scarcely fail to secure the efficient and adequate use of the available scientific personnel and the disappearance of unemployment from the scientific register.

Certain suggestions were made by Sir William Bragg in his presidential address at the anniversary meeting of the Royal Society (see NATURE, Dec. 9, 1939, p. 953). Sir William Bragg suggested that a Ministry of Science would be too formal and rigid for immediate needs and that personal and elastic methods of using knowledge were the most successful. We might well be content to bring science as a whole into close relation with government as a whole by attaching a central authority of science to the central authority of the country. The immediate application of science in any department of national affairs should be made from within that department, not from without, and the real need is for means of ensuring that the Government is able to rely on and make use of the whole range of scientific knowledge.

The value of the Royal Society as a consultative body, so strongly urged by Sir William Bragg, will be endorsed by all scientific workers, most of whom will agree that the Government could well utilize these services much more widely and fully. It is, however, the evidence of a bureaucratic outlook, indicated by the interruption of important research as a result of evacuation or other exigencies and the neglect to provide alternative accommodation, that has occasioned misgivings in the minds of scientific workers. The Advisory Research Council of the Chemical Society appears to be the first organized attempt to mobilize the research resources of the country at the universities or elsewhere, and it may be hoped that the new Advisory Council will extend the process quickly and effectively.

In the meantime scientific workers might well follow the lead of Prof. J. D. Bernal, who at the recent annual council meeting of the Association of Scientific Workers alluded to a number of scientific problems which would appear to have been overlooked in the present situation. Suggestions for investigation should not be restricted to any one field. Prof. Bernal himself referred to the need for a scientific study of 'black-out' psychology and the effects of the 'black-out' on the temperament of the community. Similarly, problems of health and hygiene raised by evacuation and other changes await investigation.

Besides the suggestion and initiation of lines of investigation, the maximum development of our scientific effort in war demands an immense educational effort, and whatever central body is established will require to have under careful consideration the propaganda of science. Science cannot be used to the best advantage without the co-operation of the whole public. The stimulation of public interest in science is of vital importance to public efficiency and technical morale, and incidentally should provide a check on the bureaucratic tendencies which have been causing concern in some quarters.

The educational aspect is of importance from another point of view also. There is perhaps the danger that in the mobilization of scientific effort and resources in support of our cause, there may be further disposition to blame science for some of the evils of war. Propaganda of the type we have indicated should do more than prevent such misunderstanding. By promoting that full understanding and sympathy which are essential in the highest technical achievements, they should also prepare the way for science to make its full contribution, undisturbed by the demands of war, to the advancement of knowledge and the enrichment of human living.

VICTORIAN SOCIALISM

The New World Order

Whether it is Attainable, How it can be Attained, and What Sort of World a World at Peace will have to be. By H. G. Wells. Pp. 192. (London: Martin Secker and Warburg, Ltd., 1940.) 6*s*. net.

"FEW human beings," says Mr. Wells in his new book, "are able to change their primary ideas after the middle thirties. They get fixed in them and drive before them no more intelligently than animals before their innate impulses." Here he does himself a great injustice. We used to wonder what panacea he would discover next. He was sure to advocate it in a brilliant and stimulating manner.

But the time comes to all of us—it came to me long ago—when our minds stiffen, and we become, as a Frenchman unkindly said, the comedians of our early convictions. The hardships of his early life have permanently embittered Mr. Wells against the class in which his genius has placed him. He sees Red when he thinks of them, and exults in the destitution which he hopes awaits them.

So, since he is far too well-informed to be a Bolshevik, he has nailed his colours to that waterlogged derelict, Fabian collectivism. We have only to make a clean sweep of emulation, ambition, love of private ownership, patriotism and pugnacity, and we shall all be as happy, progressive and intelligent as a flock of sheep. That is always the way with Utopians. Abolish all the strongest passions and instincts of human nature, and a terminal state of blessedness, an earthly paradise, will be reached.

It is pathetic to look at the row of deserted idols which we used to worship in the last century: Liberalism, Democracy, Human Perfectibility, Socialism, Communism—there are few any more to do them reverence. Liberalism, which might sweep the suburbs with the Gladstonian creed of peace and retrenchment, is content to limp feebly after Labour, and has paid the penalty. Democracy is still a fetish in America, where it means anything, from an attribute of the Deity to a method of therapeutics, except what it really is, a not very successful experiment in government. "Uric acid," I read in a New York medical journal, "is tottering on its throne. The triumphs of Democracy are not confined to politics." Elsewhere it is merely accepted from inertia, or from fear of something worse. No institution has lost in prestige so much as the House of Commons. Who now reads the dreary debates, which are not expected to turn a single vote? (Democracy as a form of society—equality of consideration—is a different matter; some other name ought to be found for it.) As for human perfectibility, nobody any longer believes in a law of progress. The fact of progress in the past—for example, in the eighteenth and nineteenth centuries—cannot be denied. But in the future? We began with faith, we went on with hope; now there is nothing left but charity.

Socialism has never recovered from giving birth to its misbegotten brat Communism. There was such a thing as Social Democracy, though Socialism and Democracy are fundamentally incompatible. Nothing could be more ignominious than the total collapse of the Social Democrats in Italy and

Germany at the first impact of Fascism. The Bolsheviks found that the Social Democrats had not got the true milk of the word, and helped in their overthrow. Mussolini and Hitler were quick to observe the signs of the times.

Communism is also practically dead. It exists in the U.S.S.R. only for export; the Government of the Soviet Republic is pure Fascism or State capitalism. It would be difficult to name any prediction of Marx that has not been falsified by history; but the most significant of all his miscalculations was that after the success of the social revolution the State would "wither away". Instead of withering away, the State in Russia is omnipotent, the most brutal and searching tyranny that the world has ever known. Communism at home is now the creed of a few *enragés* and armchair doctrinaires, and of callow boys and girls at Oxford, Cambridge and the London School of Economics.

The total failure of the prophecy that the State under Soviet Socialism would wither away is important because it affects other kinds of socialism. The inevitable result of collectivism is to deprive the citizen of all liberty, and to put him at the mercy of a horde of ignorant, indolent and insolent Jacks-in-office, who take their orders from above. This is the crucial difference between State-socialism and democracy. The bureaucracy under socialism must take their orders from above. Mr. Wells wishes his citizens to be free to speak their minds; but your bureaucrat cannot stand criticism, and will know well enough how to gag it. Mr. Wells's Gestapo are to be "sturdy and assertive". There is no fear of their being anything else.

State-capitalism can make out a plausible case for itself. But apart from the difficulty of finding skilled administrators who are willing to give their best for a very small salary (in the U.S.S.R. differential salaries are as steeply graded as in England) in the absence of competition it is most unlikely that the infinitely complicated affairs of a great industrial community would be competently handled by State officials. Such experience as is available is very discouraging to the advocates of that favourite Fabian slogan, 'a planned economy'.

I entirely agree with Mr. Wells's detestation of the new idol which has dethroned the fetishes of the Victorians—frenzied nationalism. The deification of the State is indeed a monstrous and Satanic form of idolatry. It is at present the strongest force in the world, though it must be said to the credit of the democratic countries that it has made few converts in England, France or the United States. It unfortunately commands the allegiance of some of the best as well as the worst elements in the totalitarian countries, and is therefore the greatest danger that European civilization has ever had to meet. Nevertheless, to speak of the possible "extinction of mankind" (p. 18) is surely a violent exaggeration. The worst that can happen to Europe, if we persist in what are really civil wars, waged with greater fury than the old wars of religion, is that we may be plunged into another 'dark age', which we may hope would not last six hundred years, like the welter of barbarism which followed the downfall of Græco-Roman civilization. But America and the British Dominions would survive and hand down the torch. Count Keyserling, in his "Révolution Mondiale", unaccountably forgot the not unimportant part of the human race who speak English. For I do not think that even Great Britain will either cease to exist or relapse into savagery.

I also agree with the author about the ruinous folly of the present war; but perhaps at present the less said the better on that subject.

One protest I must make in conclusion. I am not supposed to be very fond of the Roman Catholic Church, but I deprecate Mr. Wells's very harsh words about that institution. Catholicism is certainly anti-revolutionary. With its unequalled experience of human nature, that Church knows that revolutions always lead to reactions, and achieve very little at a terrible cost of human suffering. But it preserves some valuable traditions which are in some danger of being lost, including a philosophy which is far superior to modern systems. I am specially distressed to read what Mr. Wells says about Spain. I cannot understand how any decent person can deny that the Nationalists were justified in taking arms against those devils in human shape, the Spanish Reds, who, fighting under the 'hammer and sickle', and under orders from Moscow, butchered three hundred thousand men and women, a hundred thousand in Madrid alone, in an attempt to extirpate whole classes of the population. It is difficult to forget what an American eye-witness saw in the town of Ronda, near Malaga. The Reds impaled on stakes all the male inhabitants who belonged to the middle class, and while they were dying in agony compelled them to watch their wives and daughters being first violated and then burnt alive. There are scores of similar horrors equally well authenticated.

Although Mr. Wells's Utopia seems to me utterly unrealizable, no one can read the book without admiration for his earnest longing for a new and better world. As Plato said of his Republic, the type of the perfect State is laid up in heaven, and we need not inquire too curiously whether it is likely to be realized on earth. The obstacles are human sin and folly, and we shall soon have sharp enough lessons to cure all but the incurable.

W. R. INGE.

TERRESTRIAL MAGNETISM AND ELECTRICITY

Physics of the Earth, 8:
Terrestrial Magnetism and Electricity
Edited by J. A. Fleming. Contributors: J. Bartels, L. V. Berkner, J. A. Fleming, O. H. Gish, H. D. Harradon, C. A. Heiland, E. O. Hulburt, H. F. Johnston, H. E. McComb, A. G. McNish, W. J. Rooney, B. F. J. Schonland, O. W. Torreson, L. Vegard. Pp. xii + 794. (New York and London: McGraw-Hill Book Company, Inc., 1939.) 52*s*. 6*d*.

INTEREST in geophysics is widespread in the United States of America to a degree paralleled nowhere else. This still young community, now in the first flush of vigorous scientific maturity, is from practical motives actively exploring the hidden riches of its land; it is also energetically studying the land, the sea, and the air, from purely intellectual motives. One consequence is that America possesses, in the American Geophysical Union, the largest geophysical society in the world; this Union publishes an extensive and many-sided annual report, but not, as yet, any general geophysical journal. America is, however, the home of the only existing journal devoted solely to terrestrial magnetism and electricity; and the only research institution which pursues all branches of this department of geophysics, from a world-wide point of view, is also American. It is therefore fitting that the volume under review, which is probably the largest general work ever published on the subject, should come to us from across the Atlantic. It will give a valuable stimulus and help to the study of the earth's magnetism and electricity, publications on which have hitherto been rather inaccessible to workers in other fields. The volume is one of a series of reports on geophysics prepared under the auspices of the U.S. National Research Council, with which the American Geophysical Union is associated.

The book is not a systematic treatise on its subject (and there remains a need for such a treatise); it is a collective work by fourteen authors, under the editorship of Dr. J. A. Fleming, director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington —who himself, in the first chapter, on "The Earth's Magnetism and Magnetic Surveys", gives a general introduction to this, the larger of the two subjects with which the book deals. These two subjects are in fact not very intimately related to one another, and the four 'electrical' chapters—on "Atmospheric Electricity" (iv, Gish), "Instruments used in Observations of Atmospheric Electricity" (v, Torreson), "Earth-Currents" (vi, Rooney), and "Thunder-clouds, Shower-clouds and their Electrical Effects" (xii, Schonland)—might well have appeared as a separate volume; these chapters are excellently written in a systematic expository style, and almost constitute a treatise on terrestrial electricity, though of course this subject offers scope for a more detailed treatment. With their bibliography, these four chapters occupy about a quarter of the book.

No fewer than a hundred pages are devoted to a bibliographical chapter (xiii, Harradon); this is a valuable part of the book, because one of the difficulties in this, as in some other branches of geophysics, is that the original data and observations are for the most part not published in the scientific journals which have wide currency throughout the world; often they appear in separate publications or in observatory reports—the introductions or appendixes of which sometimes contain important discussions of the data, not to be found elsewhere. Moreover, owing to the border-line character of the subject (lying as it does between physics, astronomy, meteorology, geology and geography), together with the fact that there is only one journal expressly devoted to it, its current literature is scattered over an exceptionally wide collection of periodicals. Hence such a bibliography forms, as the editor states, "a most valuable research tool".

The remaining two thirds of the book includes two main groups of chapters, much more closely linked together than might appear at first sight. There are the more strictly magnetic chapters, including (with the first, already mentioned), "Magnetic Instruments" (ii, Johnston, Fleming and McComb), "Magnetic Prospecting" (iii, Heiland), "On Causes of the Earth's Magnetism and its Changes" (vii, McNish) and "Some Problems of Terrestrial Magnetism and Electricity" (viii, Bartels); and there are three chapters relating to the upper atmosphere, including one with that title (x, Hulburt), one on "Radio Exploration of the Earth's Outer Atmosphere" (ix, Berkner), and one on the "Aurora Polaris and the Upper Atmosphere" (xi, Vegard).

Workers on the many topics with which the book deals will recognize the authority of the writers who contribute the several chapters. With the exception of Chapter iii, the outlook of the book is more towards the purely scientific than the important practical aspects of the subject; it may be said to be directed to the initiation or enlightenment of physicists (and perhaps also astrophysicists) in one of the oldest of the modern sciences, which still confronts us with the mystery of Gilbert's great discovery that the earth is itself a magnet, and the but little less mysterious secular variation of the magnetic field. Apart from this, the exciting and complex problems of the subject are concerned mainly with the atmosphere; there is the semi-meteorological problem of the maintenance of the earth's negative surface charge, and the group of problems associated with the action of the sun upon the earth—for it is the sun which causes and controls the inconstant daily magnetic variation, the irregularly occurring magnetic storms and the associated auroras, and also the recently discovered group of terrestrial phenomena linked with eruptions in the solar chromosphere—radio fading and brief magnetic disturbances. The moon also, through the lunar tide which it produces in our atmosphere, plays a small but interesting part in causing the magnetic variations.

All these subjects are discussed in an interesting and authoritative way in this book, and if the voices are not always in unison, this is but a token of the need for more observation and more thought to illuminate dark questions. It is to be hoped and expected that many among the readers of this book will be led to take a share in making these "rough places plain".

S. CHAPMAN.

THE SOYA BEAN

Le soja et les industries du soja

Produits alimentaires, huile de soja, lécithine végétale, caséine végétale. Par A. Matagrin. Pp. x + 390. (Paris: Gauthier-Villars, 1939.) 60 francs.

IT is well known that the soya bean (*Glycine soja*) is one of the most valuable of cultivated crops, and this comprehensive account is of value, particularly at the present crisis, because of the numerous by-products that are obtainable from this particular plant. It is in fact one of the world's indispensable commodities.

The author records with considerable success the whole range from the cultivation of the bean to the manufacture of the latest form of by-product. In an account of the history and origin of the crop, it is pointed out that the home of the plant is eastern Asia, and in particular, Manchuria, Japan and China, from which regions, for many years, the main supply for the markets of the world was obtained. It is natural that other countries, with an eye to the valuable nature of the crop, should have endeavoured to establish it into their agricultural systems, and the most successful so far has been the United States. Here after years of trial and experiment, success has been attained in breeding types suitable to the climatic conditions, and the output of which now rivals in extent that of the Far East. In the detailed account that is given of the many attempts that have been made to establish the crop, it is noted that although the crop is stated to be adaptable and capable of growing from the equator to 50° S. and 60° N. respectively, yet success has, in the main, only been achieved on a grand scale in those countries possessing a temperate or subtropical climate.

In view of its great nutritive value, due to its high oil and protein content, there is little doubt that if the crop could be established in the tropics it would be of great value, not only because it is a valuable export crop which could be sold for cash and would, therefore, widen this field, which is so often held by cotton alone at present, but also on account of its food value. To the many who are now interested in the nutrition drive that is taking place in the British colonies its value is obvious; but it is not an easy crop to grow in the tropics. The number of varieties as indicated by the author is very great, but he brings out clearly that each variety has been evolved to meet particular types of soil and climatic conditions, and that each will usually only be found in a comparatively circumscribed area where it can enjoy these particular conditions.

The United States introduced numerous varieties and undertook prolonged selection before types suitable to American conditions were obtained. The trade demands a large round bean of a white or light colour, but unfortunately such experiments as have been made in the tropics indicate that the type of soya that grows best is one of a darker colour with a smaller and flatter bean. There is no doubt that much plant-breeding work will be needed before types really suited to the tropics can be evolved, although there is evidence that success will ultimately be obtained. Another difficulty is the short viability of the seed under tropical conditions. For this reason it is not always easy to obtain an even stand, with the result that disappointing crops are often reaped, although individual plants may often be excellent heavy bearers. The causes of this rapid loss in viability will, therefore, need to be studied and systems of storage, within the means of the peasant, evolved. Temperature is one contributing factor, as seed stored at about 60° F. keeps its viability well. It is probable that moisture content may be another factor as a natural corollary.

Another difficulty that will have to be faced is ignorance of the most attractive ways to prepare it for human consumption. Not the least valuable part of this book is the account given by the author of the different dishes that are prepared in various countries, and a campaign to educate the grower into the cooking of the bean will probably have to accompany any attempt to introduce it into his cropping system. The problem of inoculating the seed will also need to be faced, as it appears obvious that good crops cannot usually be obtained unless the right inoculum is present. This problem should not be difficult of solution, however, once a commencement has been made, as soil from an inoculated field can be used to extend the system.

Nearly half the book is devoted to accounts of the commercial products of the bean, particular attention being paid to the processes involved in the refining of the oil and its numerous uses, to the preparation of lecithin and the manufacture of vegetable casein, the demand for which has expanded greatly in recent years.

The volume is well arranged, but it is hoped that in a future edition an index will be added.

G. EVANS.

MYTHS AND MAGIC IN JAMAICA AND HAITI

Voodoo Gods

An Inquiry into Native Myths and Magic in Jamaica and Haiti. By Zora Hurston. Pp. x+290+24 plates. (London: J. M. Dent and Sons, Ltd., 1939.) 15s. net.

OBEAH in Jamaica and Voodoo in Haiti, as secret cults of the Negro, have both aroused considerable curiosity, mostly morbid. The literature relating to them is extensive, but more remarkable for its sensational statements than its ability to carry conviction as to its truth or accuracy of observation. It is, in fact, with a few notable exceptions, based on hearsay. Miss Hurston's knowledge of both cults has at least been acquired, to a great extent, at first hand; and her book is the work of a trained and experienced observer. As a member of the race she was qualified to take part in the ceremonial as an initiate, while as a pupil of Prof. Franz Boas she was able to grasp its significance as the manifestation of a form of religious belief, and view it with detachment.

Miss Hurston gives the two cults of Obeah and Voodoo their social setting in her accounts of the Negro community in Jamaica and of society and politics in the Black Republic of Haiti. The high lights of Haitian history are reached in revolution and massacre, more especially in the earlier years of the present century, leading up to occupation by the United States in 1915. The occupation lasted for nineteen years. Notwithstanding this story of bloodshed and corruption, the author sees in the recent growth of a young intelligentsia, which is making its mark in public life, the possibility of a future regeneration. There are indications of the growth of a national consciousness and of a decrease in the degree of cultural dependence on France.

In this movement towards cultural and national independence of white influence, it is thought by some, strangely enough, that Voodoo will play its part. This may seem surprising, in view of the fact that it has been usual to look upon Voodoo solely as an influence for evil, rather than as a form of spiritual belief, which could hold its own in the long run against one of the more highly organized religions, such as Christianity. This may be due to prejudice; and it has to be conceded that under the influence of the negro temperament, even Christianity itself may assume strange forms. At the same time the popular and darker view of Voodoo may not be entirely accurate.

Miss Hurston attributes much of the sensationalism which has become almost inseparable from accounts of Voodoo to a failure to understand its symbolism. Thus she maintains that the reverence accorded to the gods of the Negro in the guise of the Roman Catholic saints 'done over in black', the prominence of the snake in their cults, the erotic rites and the magical dances, and the like, are all parts of an elaborate system of symbolism, which has been, but should not be, taken at face value. Voodoo, in fact, is neither snake worship nor magic mixed up with fetichism, sacrifice and other of the more repulsive erotic and necrophilic practices of wizardry, but an organized body of pagan belief with an African pantheon.

The gods of the Haitian pantheon to a great extent are localized, and a spirit of great power in its own home may be unknown beyond a radius of fifty miles. Nevertheless some of the gods are reverenced generally; Damballa, for example, whose signature is the snake, and the goddess of love, whose position in relation to Voodoo as a fertility cult is indicated not only by the fact that she has no children, and is implacable to women, but also in that every man in Haiti is regarded as her husband. It is significant that two types of gods or spirits are recognized—the Rada or Arada, who are the good gods, to whom only pigeons and chickens are sacrificed, and the Petro, the more powerful and evil gods, who can, however, be made to do good things. To them are offered pigs, goats, sheep, cows and dogs, and even on occasion dead bodies from the tombs. The Rada are said to have been brought with the Negroes from Guinea or Dahomey; the Rada came from the Congo.

This brief mention of one feature only in Voodoo belief does less than justice to a remarkable record, which will repay close study by those who wish to understand the mentality which underlies what has been the most remarkable experiment in self-government of the black races, on their own initiative, of modern times.

HABITS AND HABITATS OF TROUT

Trout Streams

Conditions that Determine their Productivity and Suggestions for Stream and Lake Management. By Dr. Paul R. Needham. Pp. x + 233. (Ithaca, N.Y.: Comstock Publishing Co., Inc., 1938.) 3 dollars.

THIS book is an attempt to place in the hands of anglers, sportsmen, and aquatic biologists, trustworthy information relating to trout and streams in which they live.

The author is well qualified by years of experience to undertake such a work and has done it very well, not only using his own researches into stream problems but also that of many workers in his own country and in other lands where trout streams abound. The opening chapter deals largely with the various kinds of trout to be found in North America in both streams and lakes, dealing also with the habits of the different fish, followed by the chemical and physical conditions of trout streams in general and how such factors as temperature, transparency, oxygen content, and river bed play their part.

The importance of biological indicators as evidences of pollution as against that of chemical analysis is stressed—a line which is advocated in Great Britain. A very well illustrated chapter deals with trout stream animals which serve as food for trout, and should prove very useful to aquatic biologists, while it cannot fail to attract the angler with very little interest in stream organisms apart from fish. The line drawings and photographs are very clear and the tables show evidence of much work in collecting the data.

An interesting point to which attention is directed is the large numbers of land insects which are taken by trout at certain times of the year; the probable reason for this is well discussed. A very large number of stomach contents have been examined to obtain the information, and so far as streams in the central area of New York State go, the author points out the amounts of foods fall in the following percentages: caddis flies, two-winged insects and may flies, 66 per cent taken in the order stated, beetles fourth (6·6 per cent of total), spring tails, leaf hoppers, ants, bees and wasps furnish 3–6 per cent of the total, with other foods about 1 per cent, made up of crayfish, shrimps, grasshoppers, stone flies, true bugs and earthworms.

The distribution of the food in streams is dealt with under the heading of the physical conditions of the bed of the stream, stream flow and depth. The methods to be adopted in taking a census of the stream animals is described and is much on the lines adopted by workers in other countries. Stocking, propagation, and protection find a place in the book, followed by the management of trout waters gained by experience in many States.

A very useful appendix deals with the numbers and sizes of fish it is wise to introduce into streams where restocking is done, taking into account size of stream and available natural foods. Outlines are given of stream surveys and how the information should be recorded to be of use for comparison with later surveys or with those of other rivers.

There is a very extensive bibliography, which should prove very useful to those seeking fuller information on the points dealt with. The book is very well illustrated with photographs of weir fishing pools and the like, making it very attractive to the non-technical reader as well as the scientific investigator. It also gives an insight into the extent of the investigations undertaken by workers across the sea, and being written by one who, in addition to being a scientific investigator is also an angler, links up the two sides of the questions that arise.

W. RUSHTON.

CHEMISTRY FOR INTERMEDIATE EXAMINATIONS

(1) General and Inorganic Chemistry
By Dr. P. J. Durrant. Pp. x + 547. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1939.) 8*s*.

(2) A College Course of Inorganic Chemistry
By Prof. J. R. Partington. Pp. x + 658. (London: Macmillan and Co., Ltd., 1939.) 8*s*. 6*d*.

(3) Intermediate Chemistry, Inorganic and Physical
By Dr. Frederick Prescott. Pp. viii + 828. (London: University Tutorial Press, Ltd., 1939.) 12*s*. 6*d*.

THE number of chemistry text-books is becoming greater every year, and because of their number, the final selection of a suitable book is becoming increasingly difficult. During the last few years, the needs of those taking intermediate science examinations and university entrance scholarships have received special attention, and here are three new books catering for their requirements.

(1) Of the people who write text-books, the one who obtains the deepest insight into the student mind is not the teacher (who may, in fact, be very ignorant of its contents) but the examiner. He, more than any other, is familiar with the facts which are absorbed, and the heresies which persist. Dr. P. J. Durrant is not without experience as an examiner, consequently something exceptional was to be expected, and expectation has not been disappointed. The book he has written is an admirable one, and the reviewer can fully endorse the report of the publishers' reader that "the book has originality and vitality of presentation and gives a balanced and cultural appraisal of a difficult subject". Not only is this so, but the type, headings, spacing and arrangement of the text are excellent and make an immediate appeal to the eye.

The outlook is modern, Bohr's theory of atomic structure and the electronic theory of valency are introduced at an early stage, and are used as a basis for the explanation of chemical theory. The scope of the book is not limited to the syllabus of any particular examination, and it would take the student through his first year at the university. The less common elements are omitted, and only compounds of definite technical or theoretical interest are included. The only important omission is a chapter on radioactivity, which might, with advantage, have been included. Errors are extremely rare: the quantum shells (p. 116) are presumably those of uranium, where the *P* shell contains 12 not 13 electrons, and *catronic* (p. 297) is an obvious misprint.

(2) Prof. J. R. Partington's "Text-Book of Inorganic Chemistry" first appeared in 1921 and is now in its fifth edition. Successive editions have grown in size with the passing of time, until it is now too comprehensive for 'inter.-science' students. His "College Course of Inorganic Chemistry" is intended to meet the needs of the latter, especially those rather older students who are beginners, as well as younger pupils.

Although the plan and method of the "Text-Book" have naturally served as a foundation for the smaller work, much of the text has been rewritten and rearranged. Nevertheless, the familiar and successful "Partington" method is obvious throughout. The historical approach has been retained, special attention being given to the physical chemistry required at this stage, and although designed only as an intermediate text-book, it contains a very considerable amount of information and details of industrial processes.

Opinions differ as to how soon the student should begin to use and appreciate the significance of electronic formulæ. The modern tendency is to introduce them early and even to abandon the classical 'structural formulæ' entirely. The fact that here the former are sparingly used, and the latter largely retained, gives the book a somewhat old-fashioned appearance which might not entirely satisfy a modern teacher. This is the only criticism of the book, which well maintains the high "Partington" standard.

(3) Dr. F. Prescott's "Intermediate Chemistry" is described as "an entirely new book, a well-planned course of Inorganic and Physical Chemistry, based on modern ideas associated with the inter-related domains of Physics and Chemistry". The plan and balance of the book are good, but the contents are of very uneven quality, and the proof-reading has been entirely inadequate. A perusal of the book revealed twenty-one incorrect equations (and there may be more, for a systematic search was not made), many incorrect formulæ, and small errors in the text. All these mistakes are obvious and would be detected by the dullest student.

The section on the structure of the atomic nucleus and the occurrence of isotopes (pp. 252–4) contains the following sequence of statements: (*a*) the nucleus consists of protons, or particles of positive electricity, and, in most cases, electrons, the protons always being in excess; (*b*) the atomic number corresponds to the net positive charge on the nucleus; (*c*) the mass number (atomic weight) is equal to the number of protons in the nucleus; (*d*) the difference between the mass number and the atomic number is attributed to neutrons in the nucleus; (*e*) neutrons are particles with a mass nearly that of a proton; (*f*) the neutrons, being of negligible mass, may be disregarded. The table (p. 253) which gives the atomic structure of a number of selected elements does not mention the neutron, which, considering its (apparently) uncertain properties, is perhaps just as well.

'Partington' and 'Durrant' are widely contrasting books, complementary rather than competitive. Partington is historical, somewhat discursive, and (at least once) reminiscent (p. 433). Durrant is non-historical, logical, modern, and provides much tabulated information, of which Partington (p. vii) disapproves. The teacher may choose according to his tastes. J. N. SUGDEN.

BIOGEOGRAPHY IN THE U.S.S.R.

(1) Zoogeography

By I. I. Puzanov. Pp. 360 + 32. (Moscow: State Publication Office of the Commissariat for Education, 1938.) 7·80 roubles.

(2) Zoogeography of the Ukrainian Socialist Soviet Republic

By M. Sharleman. Pp. 234 +1. (Kiev: Ukrainian Academy of Sciences, 1937.) 6·60 roubles.

(3) Vegetation of the World

(Plant Geography, vol. 3.) By A. P. Il'inskij. Pp. 458. (Botanical Institute of the Academy of Sciences, Moscow-Leningrad, 1937.) 10 roubles.

ALTHOUGH the three books referred to above by no means exhaust the most important biogeographical publications that have appeared in the Soviet Union during the last few years, they deserve special notice for various reasons.

(1) Prof. Puzanov's book on zoogeography is of interest as an attempt to produce a text-book in this subject, which is still taught in too few universities, one of the reasons being the lack of suitable books for students. A brief introduction dealing with the aims and methods of zoogeography and giving a concise history of the science is followed by two general parts. The first presents a lucid discussion of the ecological principles of zoogeography; the second deals with dynamics of faunas from a geological aspect. This difficult problem is dealt with in a very clear manner, without superfluous detail, while avoiding undue simplification. The third, and the main, part of the book is devoted to regional zoogeography, that is, to descriptions of the faunas of various regions. These descriptions are based mostly on vertebrate animals, but whenever possible some data on insects, etc., are also given. A feature of the book is the abundance of very well-executed (but poorly reproduced) original illustrations of numerous animals mentioned in the text. There are even three plates in colour, but their standard is low.

On the whole, the book undoubtedly represents a very successful approach to a university text-book of zoogeography, which is as yet lacking in any language, in spite of a seriously felt need for one.

(2) Sharleman's book on the zoogeography of the Ukraine is an original treatise on the regional distribution of vertebrates of that country in connexion with their ecology and geological history. The book is written in the Ukrainian language, but Russian and English summaries are appended, while a complete list of species showing their distribution by districts, and a very full bibliography should make it very valuable for workers on the Palæarctic fauna.

(3) The book on the vegetation of the world by Il'inskij is published as the third (and concluding, but first published) volume of a series, the other two of which deal with plant geography and plant ecology respectively. The general part of the book is very brief—because the two other volumes just referred to should supply the introductory knowledge to the present one, which contains descriptions of types of vegetation by continents and natural regions. Most of the descriptions are clear, concise, based on up-to-date information and illustrated by well-reproduced photographs. All this goes to make a good text-book that should be very useful, particularly to geography students.

Indeed, it can be said that geography departments in Soviet universities are particularly fortunate in having modern text-books in both branches of biogeography, by Puzanov on animals and by Il'inskij on vegetation. The appearance of similar text-books in English would go a long way towards introducing biogeography into British and American universities, where this science is suffering from undeserved neglect. B. P. UVAROV.

MARGARINE

By Prof. J. C. Drummond,

University of London

Early History

IT is unlike the French to be unmindful of a son of their country who has rendered notable service in so important a matter as food, yet I am not aware that the achievement of Mège-Mouries is commemorated in France by a public monument or inscription or even by a street name. Equally surprising is the scanty information supplied by biographical works of reference about that most ingenious inventor. Perhaps we can attribute this to the lack of sympathy one would expect from a nation which appreciates above all other things good food and good cooks, towards one who hoped to pass off the greasy and rather unpalatable products of his laboratory as butter. Whatever the reason for such neglect, the fact remains that the French might well be proud to claim the inventor who made possible one of the greatest food industries of our time.

It is often erroneously believed that Mège-Mouries set out to concoct a substitute for butter. It is true that he was stimulated by the desire of the Victualling Department of the French Navy to find such a substitute ; but he himself was more ambitious. He attempted to produce butter itself, and that by a series of laboratory treatments that he thought would reproduce exactly the changes by which he believed body fat to be converted into milk fat in the animal body. His laborious process, in which beef fat was digested at blood heat, first with macerated sheep's stomach and then with chopped cow's udder and milk, actually gave him nothing more unusual than the softer portion of the original fat, carrying, presumably, some traces of a milky flavour. Nevertheless, in the early days he was quite satisfied that he had made butter. Others, less optimistic, were content to believe that he had solved the problem of preparing an edible substitute for butter, and for this achievement he was honoured in 1870 by Napoleon III.

Had it not been for the Franco-Prussian War, it is probable that France would have led the world in the technical development of the new process. As it happened, the opportunity was seized in the United States and in Holland. In a remarkably short time factories were springing up in these countries for the manufacture of what was then called 'butterine'. It was soon found that Mège-Mouries's complicated digestion was quite unnecessary, and that all it was necessary to do was to mix as thoroughly as possible with skimmed milk, preferably slightly sour, a fat of the appropriate melting point. On separating the fat again it was found to have acquired a buttery taste. It could then be 'worked', salted and coloured to taste.

Manufacture in Great Britain lagged far behind in the seventies. So far as can be judged from the contemporary press, the home-produced material was, moreover, of very inferior quality. Most of it was made in small, dirty, 'back-street' premises under highly insanitary conditions. To a large extent it was knowledge of these facts that gave 'butterine' so bad a reputation at that time. The English public was ready to believe any fantastic yarn about the doubtful nature of the fats used by the manufacturers, and they also suspected, often with more reason, that a good deal of the despised stuff was employed as an adulterant for butter. The passing of the Margarine Act in 1887 did something to allay uneasiness ; nevertheless, the reputation of the new food remained an unsavoury one for a good many years.

Improvements in Manufacture

Then in 1889, Otto Monsted opened the first up-to-date factory in Great Britain. The pioneers were faced with a truly formidable task. Prejudice against margarine was at that time shared by rich and poor alike, and opposition from certain other trades, particularly the dairy industry, was vigorous and none too scrupulous. The product Monsted turned out was made from that fraction of beef fat which is known as 'oleo' or 'premier jus'. It was, in fact, a highly digestible fat possessing a calorific value equivalent to that of ordinary butter and, what was of great importance although unknown at the time, its vitamin A, and probably also its vitamin D, content was by no means negligible. It is probable that its nutritive value was not far below that of ordinary 'average' butter ; but it is difficult to make a proper estimate because it is a curious fact that an extensive modern literature on the vitamin contents of foods does not give us any information as to the A and D value of the common edible body fats such as those of beef or mutton.

By comparison with our modern margarines these primitive materials were undoubtedly very crude. They were inclined to be unpleasantly greasy, to stick to the knife, and to spread in a manner unattractive to those used to butter. Moreover, they often had a 'fatty' taste and smell which many people disliked.

No problem has given the margarine manufacturers more trouble than that of producing a texture resembling that of dairy butter. The introduction about 1890 into margarine manufacture of vegetable oils suitable for blending with 'oleo' helped them to some extent; but it was not until some years of the new century had passed that their fortunes turned. By this time the small producer was dropping out of the picture and with him many brands of dubious quality which had served to keep alive an unenviable reputation. To an ever-increasing extent manufacture was passing into the hands of large commercial organizations guided by directorates not only anxious to provide the consumer with an article of high quality, but also prepared to spend very large sums of money on scientific and technical research to that end. One by one the problems were attacked and solved. Care in the selection of oils for blending; improved methods of emulsifying the mixture with pretreated separated milk; controlled crystallization of the final product to get the right 'grain'; special precautions to be taken in 'working' a mixture differing in many subtle characteristics from butter; such knowledge, gained by patient and costly research, brought about remarkable improvements in respect of that almost indefinable but all-important character of texture. Chemists, biochemists and bacteriologists collaborated to select the appropriate bacterial flora which would produce in the separated milk just the right blend of substances necessary to impart to the margarine that elusive 'butter flavour'. Others ingeniously prepared chemical flavouring substances to serve the same end.

Another important milestone was the introduction of 'hardened' vegetable and animal fats.

Such have been the labours that have gone to produce the high quality of the popular butter substitute we know to-day.

VITAMIN REINFORCEMENTS

The period of the War of 1914–18 is very important in the history of margarine. At that time most authorities on dietetics regarded margarine as a reasonably good substitute for butter, because it was well digested and for all practical purposes provided the same heat-producing power. It was one of the cheaper forms of energy.

During the latter part of the War, however, the importance of the fat-soluble vitamins, discovered a few years before, gradually came to be recognized. The nutritive worth of edible fats could no longer be assessed solely in terms of digestibility and energy equivalents. It was necessary to ascertain whether they would also provide the newly discovered constituents. Butter was found to contain them. On the other hand, most of the vegetable oils and fats then being used more and more extensively in margarine manufacture, as well as the hardened fats which had come into use soon after 1910, were found to be defective in this respect. Following up the obvious line these observations indicated, the late Prof. W. D. Halliburton and I examined a number of typical margarines and found that their nutritive value for the growing animal was determined by the vitamin contents of the constituent oils and fats. Margarines prepared almost solely from beef 'oleo' appeared to be as nutritive as butter, whereas the vegetable oil margarines, in spite of being excellently assimilated, did not supply the fat-soluble 'growth-promoting' factors needed by the young animal.

These observations made little impression on the margarine industry at the time. Such reaction as there was consisted of frank scepticism. Some people challenged the conclusion that vegetable oil margarines were devoid of vitamins by directing attention to the fact that milk, which in a vague sort of way was thought to be one of the richest sources of the accessory factors, was employed in the manufacture of the products. Others refused to acknowledge that experiments on rats could have any bearing on human nutrition. Others, again, argued that such small differences in composition of a single article of diet could scarcely be of any practical significance. Nearly ten years passed before serious attention was given to the matter. Then, at last, the margarine manufacturers moved. Many of the earlier attempts to raise the nutritive value of their products by the addition of vitamin preparations were failures. For the most part they were attempting to employ materials and concentrates prepared from cod liver oil. It was not a difficult matter to add sufficient of such supplements to bring the vitamin value of margarine up to that of an 'average' butter; but it was found that such additions almost invariably ruined the flavour and palatability besides materially increasing the cost.

The first real progress was made after the discovery of the method for preparing pure crystalline vitamin D_2 from ergosterol. It then became possible to raise the antirachitic value of a margarine at a very slight cost without affecting edibility in the slightest. To confer on margarine a vitamin D activity of 30 units per ounce, it was necessary to add only one ounce of vitamin D_2 (calciferol) to 120 tons of margarine. What was next required was a cheap and effective source of vitamin A. It was found in one of the by-products of the whaling industry operating in Antarctic waters. Like other mammals, the whale stores considerable amounts of vitamin A group in its liver, though on the other hand it has curiously small reserves of D. The development of the factory-ship organization in the far southern waters made available large quantities of whale liver fat. It had the advantage not only of being valuable as a source of A but also of yielding material which could be employed without impairing the flavour of the finished margarine. By employing this supplement and at the same time adding artificially prepared vitamin D, the production of a satisfactory 'vitaminized' margarine for the ordinary market was achieved. Brands prepared with such additions first came on the market about six years ago. Not unexpectedly, they aroused a good deal of hostility from the butter industry, and there have been sharp controversies between the rival interests. With the many and widely differing aspects of these controversies we cannot be concerned here. Suffice it to say that in one country at least a rather bitter trade war has been terminated by a government-inspired 'gentleman's agreement' to 'live and let live'.

More recently, success has rewarded efforts to prepare from fish liver oils concentrates of A and D suitable for adding to margarine. They are prepared from liver oils of very high initial potency. So small an addition is required that the palatability of the final product is unaffected, and, what is so important, the cost is almost negligible.

MARGARINE IN THE NATION'S DIET

It is very important, particularly at a time like the present, to try to get such a valuable foodstuff as margarine into proper perspective with the diet of the nation. In 1938, a year in which butter was, generally speaking, cheap, the weighted average consumption per head of the population of Great Britain was 7·6 oz. a week, while the corresponding figure for margarine was 2·3 oz. Even the people classified in the poorest category of the population purchased, on an average, 4·5 oz. of butter per head per week.

If we take, as a peace-time basis for our argument, 10 oz. per week as a rough and ready estimate of the consumption of butter and margarine by the people of Great Britain in 1938, and if we also assume that the whole supply had the same vitamin content as an 'average' butter, we find a weekly intake of, approximately, 5,500 units of A and 150 units of D. Had the whole ten ounces been an 'average' vitamin-reinforced margarine, the intake of A would have been somewhat less, whereas the D supply might have been nearly twice as large. In either event, these quantities approximate more closely to the requirements of the individual for one day than to those for a whole week.

In other words, the 'average' individual is more dependent on milk, eggs, green vegetables, etc., than on butter and 'vitaminized' margarine for vitamins A and D.

It is very important to remember, therefore, that the consumption of these alternative sources of fat-soluble vitamins is pitifully small among the poorer sections of the community. Under such conditions the question of the vitamin content of margarine assumes greater importance.

A consumption of 4·5 oz. of butter weekly—which is slightly more than the official ration—together with the balance of 5·5 oz.—assuming once again a total intake of 10 oz.—in the form of a 'non-vitaminized' margarine, would provide a mere 2,500 units of A and 70 of D. That is scarcely a conspicuous contribution to what the body requires. Such figures signify that a good proportion of the poorer people were receiving insufficient of these two vitamins under the relatively good conditions prevailing in 1938. There is evidence from other sources that this was so.

The deficiency was, of course, very much more serious at the end of the War of 1914–18, when rationing restricted weekly supplies to 1 oz. of butter and 4 oz. of margarine, none of the latter being 'vitaminized'. From these foods the individual could count on little more than 550 units of A and 15 units of D in a week—about one tenth of an adult's daily needs!

With rationing of butter in force, and having in mind the limited purchasing power of the poorer sections of the community, the desirability of enriching all margarines with vitamins A and D supplements must appear obvious.

At the present time a large proportion of the margarine sold over retail counters is so enriched. Unfortunately, there does not appear to be uniformity between the various brands, although for the purpose of general estimates such as have been made in this article, the content of an 'average' vitaminized product can be taken as 450 units of A and 30 units of D per ounce. A weekly supplement to the butter ration of 6 oz. of reinforced margarine could be regarded, therefore, as adding some 2,700 units of A and 180 units of D to the diet. It is certainly nothing to boast about; but one must remember how valuable is every unit where poverty diets well below the marginal nutritional level are concerned.

It will not be possible to plead ignorance this time if vitamin deficiency is allowed to be responsible for a decline in general health such as occurred during the years of 1914–18.

TOWN'S REFUSE AS A SOURCE OF SOIL ORGANIC MATTER

BY DR. E. H. TRIPP

ALTHOUGH animal and vegetable wastes have been used as manure for untold ages, and their good effect on soil fertility has never been in doubt, chemists and microbiologists would be the first to confess that there are many gaps in our knowledge of their modes of action. To take farmyard manure—still without a rival—we know the value of the plant foods it contains, and its remarkable power, after decomposition, of promoting and conserving the granular structure of the top soil, thereby making it porous to air, absorptive and retentive of moisture. How this physical effect is brought about is still largely a matter of hypothesis ; and generally speaking, we know nothing of the sequence of changes that follow the incorporation of farmyard manure with the top soil.

The solution of such questions would help in determining beforehand the possibly beneficial action of many other organic substances that are or might be available to eke out our diminishing supplies of farmyard and stable manures. At the present time, when it is planned to convert millions of acres of inferior grassland into arable, the provision of additional supplies of humus-forming material becomes exceptionally important.

A potential source of supply of organic manure is the refuse of cities and large towns that is now carted away and dumped on to waste land or into the sea. The composition and production of such refuse have, *inter alia*, been investigated by a sub-committee of the Institute of Public Cleansing, and reported upon by H. Edridge (1937). Samples of the refuse collected from 485,894 houses, with 2·082 million people, contained an average of 13·23 per cent of vegetable and putrescible matter, corresponding to more than one million tons of such matter contained in the estimated total of 8·3 million tons for the entire annual output of the United Kingdom. The percentage of organic matter in the refuse varied considerably with the class of dwelling ; that from artisans was 9·96, from the middle class 15·33, and from the 'better' class 16·62. Paper averaged 14 29 per cent, and rags 1·89 per cent.

The question arises, therefore, whether such refuse can be used as an organic manure, either directly or after processing. As criteria of suitability the main considerations are : contents of nitrogen, cellulose and lignin, and rate of decomposition in the soil. Although little work has been done in these directions, a few practical men have been forestalling scientific inquiry. The Corporation of St. Albans, Herts, is producing material that is reported to have given good results on neighbouring farm land, and the Royal Borough of Kensington is disposing of all its refuse to a private company that is converting it into an organic manure in a plant designed to treat 250 tons a day, situated at Wood Lane, London, W. A similar plant is to be in operation at Harrow early in 1940. The process is simple : grosser solids like metal containers, glass, and paper are picked out by hand on moving belts ; the material is crushed, sprayed with a culture of nitrogen-fixing bacteria, and then allowed to ferment, aerobically and anaerobically, for sixteen days in large chambers. The product has little odour, and is a coarse brown powder containing about 30 per cent of organic matter (with about 1 per cent of nitrogen), 40 per cent of inorganic solids, and 30 per cent of moisture.

Large-scale replicated experiments to determine its manurial value were undertaken by the Rothamsted Experimental Station on a wide variety of soils at Rothamsted on kale, Woburn on sugar-beet, Tunstall (Suffolk) and Siddlesham (Sussex) on potatoes, and at High Halstow (Kent) on mangolds. The treated town's refuse (termed 'Hyganic') was compared with farmyard manure, rape-dust, and sulphate of ammonia in single and double doses. The chief interest lies in the comparison with farmyard manure at Rothamsted where, on an equal nitrogen basis, 'Hyganic' proved superior three times out of four ; and at Woburn where, although the differences in terms of sugar per acre were not statistically significant, there was an advantage of 3 cwt. per acre of sugar in favour of 'Hyganic' when double dressings (1·6 cwt. nitrogen per acre) were applied. The value of the nitrogen in the manure was found to be nearly equal to one half that in sulphate of ammonia.

The results apply to the year of application only (residual effects were not examined), but they show that the organic matter in the town's refuse decomposes quickly, rendering the contained nitrogen readily available. The relatively rapid decomposition in the soil may well be associated with the beneficial effect on soil texture, which has been observed by market-gardeners and others, thus supporting Geltzer's generalization that the rate of decomposition of organic matter in a soil is directly related to the stability of the larger soil-aggregates that determine a good tilth.

MAGNETISM AND THE STRUCTURE OF MATTER*

By DR. KATHLEEN LONSDALE
ROYAL INSTITUTION, LONDON

THE first attempts at an explanation of magnetic phenomena were mainly concerned with the problem of action at a distance, but later the centre of interest shifted to the mechanism within the magnetized body which came into action under the influence of the external field. After the discovery by Oersted of the magnetic effect of an electric current, Ampère suggested in 1825 that a hypothesis of molecular currents might explain induced and permanent magnetization. At the time, only ferromagnetic phenomena were known, but the design of powerful electromagnets enabled Faraday to make the fundamental discovery that all matter is affected to a greater or less degree in a magnetic field. There are two broad types of behaviour: diamagnetic substances tend to move from the stronger to the weaker part of a non-uniform field and to set their longest dimension at right angles to the lines of force; paramagnetic substances move from the weaker to the stronger part of a field and set their length along the lines of force. Faraday showed that the resultant flux (lines of force per square centimetre) within a diamagnetic body must be less, while the flux within a paramagnetic body must be greater, than that in the external field. That means that the induced magnetization within a diamagnetic body opposes the inducing field, while that within a paramagnetic body reinforces the field.

Weber suggested in 1854 that if electric currents could exist within molecules, then substances might be divided into two classes according as to whether their molecules had a resultant magnetic moment due to circulating currents or not. Only the former could show paramagnetism. This is the basis of the Langevin theory. The atom is now known to be built up of particles of a certain mass and charge, the velocity and distribution of which can be varied under certain conditions. Magnetism is a property of these ultimate particles, because a moving charged particle is equivalent to a current in a circuit and therefore possesses a magnetic moment.

DIAMAGNETISM

Diamagnetism is due to induced currents within the atom, these induced currents taking the form of a modification of the existing motion of the electrons. The orbits precess about the field direction, and this extra electronic motion gives rise to a magnetic moment the value of which depends on the field strength, the electronic mass and charge, and the projected areas of the electronic orbits. The gram atomic susceptibility (ratio of the intensity of magnetization per gram atom to the inducing field) is entirely governed therefore by the distribution of electron density in the atom. All atoms show diamagnetism, but unless the resultant angular momentum of the atom is zero in the absence of a field, paramagnetism or ferromagnetism will also be present and the diamagnetism is relatively unimportant.

The susceptibilities of the inert gases have been measured and compared with those calculated from spectroscopic knowledge of the electron density distribution. Other atoms or groups of atoms may attain zero resultant angular momentum in three principal ways. In *ionic compounds* the component atoms may give or accept electrons, so that the external shells of each are completed. This occurs, for example, in the alkali halides. The susceptibilities of such polar compounds are additive, but when the compounds are dissolved in water, only dilute solutions show additivity. In concentrated solutions the ions not only depolymerize the water, but also form hydrates and other complexes. The electronic structure both of the ions and of the water molecules is deformed, with a consequent change of susceptibility. The structures of light and heavy water and of water of crystallization are also being studied by measurements of susceptibility.

In *homopolar compounds* the atoms share electrons, thus completing their electron shells or pairing off their odd electron spins. The diatomic molecules H_2, Cl_2, Br_2, etc., are diamagnetic because the electron spin of one atom is antiparallel to that of the other. In O_2, however, the electron spins are parallel, giving rise to a strong paramagnetism. Nearly all organic compounds are diamagnetic, and Pascal has shown that their molecular susceptibilities obey an additive rule $\chi_M = \Sigma\chi_A + \lambda$, where λ is a factor which makes allowance for the different kinds of valency bonds. This rule can be used for the determination of chemical constitution in doubtful cases, and for the study of polymerization. Complex compounds are frequently diamagnetic because the effective atomic number of the complex group is equal to that of an inert gas, but this alone is not a sufficient criterion. The state of the electrons taking part in the formation of chemical bonds;

---

* Substance of a special course of lectures for students, given at the Royal Institution on November 29, December 6 and 13, 1939.

is important. Measurements of susceptibility are now being used to investigate the constituents of natural products, including blood.

In *metallic compounds* the valency electrons become free electrons having a small resultant paramagnetism, while the positive metallic ions will be diamagnetic if their outer shell is closed. Thus many metals are weakly paramagnetic or diamagnetic. In some semi-metals such as bismuth, antimony and graphitic carbon, the binding electrons are not really free; their energy states bear a definite relation to the crystal structure and this results in high diamagnetism and large anisotropy, both of which disappear on melting or can be radically changed by the solution in the solid of small quantities of other elements.

Normally, diamagnetism is independent of temperature and of change of state, but a metal which becomes superconducting at very low temperatures always becomes also strongly diamagnetic. Except for a very small surface region, no flux can penetrate an ideal superconductor, the permeability being zero throughout the interior of the metal and changing from zero to unity in a region of about 1000 A. width below the surface. The supercurrent, which exists only in this surface region, is according to the theory of London a stationary current dependent upon the presence of a magnetic field, similar to that in a large diamagnetic atom. In wires, films or particles of dimensions comparable with 1000 A., the susceptibility is only a fraction of that of the bulk superconductor. Slater has suggested a molecular model for the theory of London on the basis of semi-bound electrons with very large wave-functions, and explains the 'threshold field' as that value at which the Larmor precession energy becomes comparable with the 'atomic' energy.

In aromatic organic compounds there are electrons which occupy large plane orbits, and this results in a large molecular anisotropy. From the principal susceptibilities of single crystals of such substances, it is sometimes possible to determine the orientations of the molecules, or if the crystal structure is known to deduce the electron distribution in the molecule.

PARAMAGNETISM AND FERROMAGNETISM

Any atom or ion will be paramagnetic that does not succeed in completing its outer shell or in pairing off its electrons. The inner closed shells contribute only to a correcting diamagnetism. The resultant magnetic moment of the atom is measured in Bohr magnetons (μ_B) and is dependent upon the motion and distribution of the odd electrons, that is, upon their momenta. Electrons can have orbital (L) and spin (S) momenta, which combine to give a resultant angular momentum (J). All of these are quantized, that is, they can only have certain values. The angle between the resultant angular momentum and the magnetic field direction can also only have $(2J + 1)$ discrete values. The gyromagnetic ratio, which is the ratio of angular momentum to magnetic moment, is $2m/e$ for orbital motion, m/e for spin motion and $2m/ge$ for the whole atom, where g, the Landé splitting factor, is dependent only on L, S and J.

In the Gerlach-Stern experiment a stream of free atoms from an electric oven passes through an inhomogeneous magnetic field and is received on a cold glass plate, the vapour pressure in the apparatus being low so that no collisions take place. Paramagnetic atoms will be both orientated and deflected, giving $(2J + 1)$ separate traces, the separation of which depends upon g. Hence the one experiment gives both angular momentum and magnetic moment of free atoms. Data so obtained agree well with those determined from spectroscopic measurements. A modification of the method can give the spin momentum and magnetic moment of the nucleus. Even for large atoms containing many protons and neutrons the largest nuclear spin observed is 9/2, indicating that the nucleus itself may have a shell structure, only uncompensated particles contributing to the resultant momentum. The magnetic moment of the proton is 2·85 nuclear magnetons ($\mu_N = \frac{1}{1840}\mu_B$), from which it appears that the proton itself may not be a single particle.

When the effective magnetic moments of bulk substances containing paramagnetic ions are measured, it is found that the rare earth salts give results which agree well with theory, whereas salts of the transition series have susceptibilities considerably lower than theoretical values. This is due to quenching of the orbital moments in the latter by electric fields due to neighbouring atoms; this effect may introduce asymmetry in the case of crystalline fields. The incomplete group in rare earth ions is largely shielded from such interaction by an outer completed shell.

Paramagnetic saturation can only be approached at very low temperatures using enormous fields and substances of large magnetic moment. At ordinary temperatures the susceptibility varies inversely with absolute temperature (Curie's law) or with the excess temperature above a critical value θ (Curie-Weiss law). In the latter case it appears as if, within the substance, there were an extra field adding to the effect of the external field. This inner field is much too large to be of purely magnetic origin and is attributed to exchange interaction between electrons of neighbouring atoms.

Below the Curie point, θ, it is possible for a spontaneous magnetization to exist in certain cases even in the absence of an external field. This magnetization, which varies from complete saturation at 0° A. to zero at the Curie point, is identified with the 'saturation' intensity of ferromagnetic substances appropriate to each temperature. Above their Curie points, all ferromagnetic substances are paramagnetic and obey the Curie-Weiss law. The intrinsic magnetization of a ferromagnetic is uniform in direction only throughout small regions or domains the average size of which is about 10^{-8} c.c., containing some 10^{15} atoms. The directions of magnetization of the various domains may be random and their resultant nil, but a small field is usually sufficient to align moments of individual domains. Single crystals have certain axes of easy magnetization which would appear to be the natural directions of spontaneous magnetization. Measurements of the gyromagnetic ratio prove that the elementary magnetic carrier is the electron spin. Heisenberg showed that intrinsic fields of the right order of size could arise from exchange interaction between electron spins. The condition for a large-scale alignment of spins is that the ratio of the distance between neighbouring atoms to the radius of the energy shell in which uncompensated electron spins exist shall lie within certain limits. The ratio has the right value for iron, cobalt, nickel, and for some of the rare earth metals; chromium and manganese lie just outside the range, but certain compounds and alloys containing these elements (notably the Heusler alloys) are ferromagnetic.

The first few atoms of an impurity do not markedly affect polycrystalline ferromagnetic materials, but if the number of dissolved atoms becomes larger than the number of domains, then even very small percentages of carbon, oxygen or sulphur can greatly lower permeability and increase hysteresis. The addition of silicon has the effect of causing these impurities to crystallize out in forms in which they are relatively less harmful. Much work has been done on the technical side in these directions, and in the preparation of 'soft' and 'hard' magnetic materials. Recent X-ray work has revealed why it is that alloys prepared under certain conditions of heat treatment make excellent permanent magnet material.

OBITUARY

Mr. Wilfred Trotter, F.R.S.

IN the recent autumn the Royal Society has suffered the loss of both of its fellows whose work lay in surgery, Harvey Cushing of America, who died on October 7, 1939, and Wilfred Trotter of London, who died on November 25 at the age of sixty-seven. Each had done conspicuous work in the surgery of the brain, approaching their problems with physiological thought, and Cushing's name will always be remembered for the studies by himself and his pupils on the pituitary gland and on the microscopic structure of brain tumours in reference to their ways of malignant growth. He was a pioneer in cerebral surgery in America, and his supreme powers both as an operator and as a scientific thinker soon gathered around him at Harvard a school of workers who will assuredly maintain the energetic influence left by Harvey Cushing's mind. The possibility of this broadly based success was a reward of the changes deliberately planned in American universities in order to enable a leader in medicine or surgery to receive all such laboratory and other advantages as a professor of physiology would expect in his department for the progress of scientific work and teaching.

Trotter was too early in England for such an opportunity, and much of his life was perforce spent in individualistic effort as a consulting surgeon. At University College Hospital he inherited the field of Sir Victor Horsley's work and soon proved himself to be a master of the surgery of the brain and of the thyroid gland. He wrote a general analysis of the physiological processes involved in cerebral concussion which influenced surgical thought widely. A new approach to the difficult tumours of the pharynx was devised by him, and in this and equally in all the familiar operations of surgery he worked with such technical perfection and delicate care of every detail for the welfare of both wound and patient that none could surpass his results. Practice as a London consultant grew rapidly, and from 1932 onwards Trotter had the honour of being sergeant surgeon in succession to three kings of England. But at that zenith of individual success he made a choice which to ordinary ambition seemed utterly paradoxical. His health was becoming unequal to the fullest strain of work, and so about 1934 he withdrew, not from unpaid hospital duties at his medical school, but from all private practice. He wished, while he still could, to teach the young men.

Trotter's influence on those around him at University College Hospital had at all times been profound. The fine lines of his face and the quiet perfection of everything said or done by him were united with a keenness of intellect that was stirringly eager to aid the minds of others and never stood aloof. His method was like that ascribed to Socrates, a conversation in which he would relentlessly, yet never with discourtesy or overbearing force, compel those sharing it to think afresh, to see through time-worn phrases, and to discover the foundations, if any, of their beliefs. Any question would serve him for the method—surgical, medical, ethical, or artistic; and a light irony would always keep the talk at human levels. He seemed to have realized completely the old precept "Know thyself", and through that discipline to have gained the power to influence the minds of all others.

Trotter's intense interest in the human mind inspired the first as well as what chanced to be the last of his publications ("Has the Intellect a Function ?", *Lancet*; June 24, 1939). In 1905, when demonstrator of anatomy at his medical school and waiting in the hope of appointment to the surgical staff, he produced none of the conventional apprentice papers in surgery but wrote for the *Sociological Review* an illuminating article on herd instinct. This was enlarged and republished in 1915 as a small book analysing the mentalities of nations then at war. Describing himself in it as a biological psychologist, he sought to compare with objective detachment the workings of the mind and of instinct in man and in animals, and he found associated with the gregariousness of man and of many creatures a powerful herd instinct that could be used to explain much in human behaviour.

But his surgical training and his exact sense of scientific values made Trotter reluctant for speculation that could not be tested by observation, and his later writings on such questions were those of a wise philosopher surveying the world of medicine rather than of a formal psychologist. The question of pain often occupied his thoughts, and during the earlier period when he had some leisure for experimental work he published in the *Journal of Physiology*, 1909, an important series of observations made with Morriston Davies on the nature of the sensations found during restoration of function of various skin nerves that had been deliberately cut in themselves. This work was done to test the generalization as to the existence of separate epicritic and protopathic nerves that Head and Rivers had made upon one experiment. Afterwards Trotter himself suggested a most attractive generalization, that pain arose when body tissues were in contact with naked and uninsulated nerve fibres; but then he had no leisure to test his view experimentally nor pupils to whom he could give the problem.

For a period, 1935–37, that was too brief and too late for work of his own, Trotter accepted the post of director of the Surgical Unit at University College Hospital as a temporary successor on the retirement of Prof. Choyce, because he regarded the welfare of such departments as of the highest value to a medical school. His eminence as a surgeon naturally gave him a seat for many years on the Council of the Royal College of Surgeons. He also served clinical science by his membership of the Medical Research Council during 1929–1933; and he was twice chosen for the Council of the Royal Society, on the second occasion being named as a vice-president. Trotter never avoided committee work, for he was eager to guide practical progress. But he cared little to popularize his name in general surgery, and the writings by which he became more widely known in the medical world were his short papers and addresses on the general theme of medical science. They gave his message of the need for clear thinking. But few men have the power to think as penetratingly as Trotter could always do, or to state their thoughts with such clearness and perfection of language.

T. R. E.

WE regret to announce the following deaths:

Mr. W. A. S. Calder, president of the Institute of Chemistry, on January 6.

Dr. W. B. Worthington, formerly engineer-in-chief of the Midland Railway, president of the Institution of Civil Engineers during 1921–22, on December 29, aged eighty-five years.

NEWS AND VIEWS

Margarine

Now that rationing of certain articles of diet has begun in Great Britain, interest is naturally being concentrated on substitute foodstuffs. In the recent past, margarine has not enjoyed much popularity, even among the poorer people of the country. This has been due partly to a not too savoury history and partly, no doubt, to ignorance of its constitution and dietetic value. Present-day brands of margarine cannot be considered in any way *Ersatz* butter, but will, once prejudice has been eliminated by experience, prove complementary to the adequate amount of butter allowed under the present rationing scheme. At present, margarine is not being rationed; therefore until it becomes necessary to ration cooking fats, its greatest value lies in eking out our butter supplies.

The plain statement of facts about margarine in an article beginning on p. 53 of this issue of NATURE, by Prof. J. C. Drummond, should do much to allay suspicion of, and counteract ill-founded prejudice against, this important commodity. Prof. Drummond has been University professor of biochemistry in University College, London, since 1922, and his deep practical knowledge of biochemical and physiological problems is now being utilized by the Ministry of Food, to which he is attached. His account of the early history and later improvements of manufacture of margarine will be read with interest, while the description of vitamin reinforcements should convince those still sceptical that margarine is a valuable article of food not only from the point of view of nutrition but also from that of health.

Sir John Reith, Minister of Information

SIR JOHN REITH, chairman of Imperial Airways, Ltd., has been appointed Minister of Information in succession to Lord Macmillan; the way is thus open to bring into the House of Commons the minister in charge of a department the working of which has been severely criticized ever since it began to function on the outbreak of war. Sir John is perhaps better known as the director-general during 1927–38 of the British Broadcasting Corporation, having been managing director of the British Broadcasting Company which preceded it. Hence he was largely responsible for the guidance and development of the broadcasting service of Great Britain in its early and critical days, when its functions were ill-defined and its merits as a vehicle of entertainment, of news and of education for the masses were much debated.

Before he became associated with broadcasting, Sir John was for a short period general manager of the well-known engineering firm, Wm. Beardmore and Co., Ltd. This followed Government posts in charge of munition contracts after and during the War of 1914–18, in which he served with the Royal Engineers. Sir John is an engineer by profession, having passed through the Royal Technical College, Glasgow, and served a five-years engineering apprenticeship in Glasgow. He is a member of the Institution of Civil Engineers. While his professional knowledge was no doubt of service during his eleven years with the B.B.C., it was his forceful character and administrative ability which were outstanding; these, with his experience of public affairs and the Press, will be invaluable assets in the chief of a young department which is capable of making invaluable contributions to the influence and prestige of Great Britain and to the morale of the people at home.

The British Association

THE General Committee and the Council of the British Association held a joint meeting last week, at which Sir Albert Seward, the retiring president, handed over the chair of the Association to his successor, Sir Richard Gregory. It was reported that, by agreement between the authorities at Newcastle and the general officers of the Association, arrangements for the meeting of the Association which had been appointed to take place in that city next September were in abeyance, and that a meeting there was not contemplated, save in the event of an early peace.

The Committee of the Association therefore proceeded to a discussion of the desirability and possibilities of a meeting being held, in some modified form, and in some other place. As to desirability, there was general agreement; as to possibilities and places, various suggestions were put forward, and in the upshot the general officers were instructed to make the best arrangements they can for some sort of an abbreviated meeting. Whether as part of such a meeting, or independently, the potential activities of the Division for the Social and International Relations of Science will be taken into consideration. No action has been taken to appoint new sectional officers for the year; but the general officers were instructed to consult those who held such offices last year, and any others whose advice and help would be appropriate.

Scientific Workers and the Armed Forces

THE Ministry of Labour and National Service announces that the operation of the Schedule of Reserved Occupations is being relaxed to enable men at or above the age of reservation in scientific occupations to volunteer in approved cases for service in the Forces. Such men have previously been able to join the Forces in their professional capacity, and the present relaxation of the schedule is designed to enable those whose services are not required in a professional capacity in the Forces or as civilians to volunteer for other forms of service. To secure that scientific workers shall not be withdrawn from civil work to the detriment of the national interest, and that an adequate reserve of scientific workers is maintained for essential services, the Scientific Research Committee of the Central Register Advisory Council will consider applications from volunteers with the view of ensuring that relaxation is granted only in suitable cases. Any reserved scientific worker who wishes to volunteer should apply to the Ministry of Labour and National Service (National Service Department), Montagu House, Whitehall, S.W.1.

Scientific Workers and the War

A SYMPOSIUM, organized by the Faculty of Science of Marx House, Clerkenwell Green, London, E.C.1, was held during the week-end of December 30–31, the title of the meeting being "The Position of Science and Scientists in the War Situation". No adequate assessment of the effect of the war is possible without some knowledge of the economic background, and this was afforded by Maurice Dobb in a paper entitled "The Economics of War Capitalism". It was with this background that the meeting held a discussion on the effects of the war on university research and education, opened by Prof. H. Levy. It was argued that the cost of the social services would be cut, and in this respect, the maintenance of the universities on the present scale would be regarded as an unnecessary luxury, with adverse effects on staff, students, and standards of education. Mr. Roscoe Clarke, in discussing the scientific social services, showed that the incidence of the same problems has been felt in the medical services. The emergency medical schemes have cut right across the normal medical services, already dislocated by the evacuation of schoolchildren. Prof. J. D. Bernal, in the concluding paper, dealt with the status of the man of science. The historical role of science in the development of capitalism was analysed, and the effect of the functions of the scientific worker on his status discussed; at the present time, the existing system cannot use to the full the science it has itself brought into being.

The general tone of the discussion as a whole was that scientific workers are more and more beginning to feel dissatisfied with the role of science and its present applications to human welfare, and that a material change, if not a complete break, will have to be made with the present economic system before science can be fully utilized. Concern at the insecurity of their own position in the immediate future is leading scientific workers to the view that a new type of scientific organization, based on the experience of the trade unions in the defence of the economic and cultural interests of large masses of the population, is becoming necessary.

The Earthquake in Turkey

As the railway between Sivas and the ruins of Erzinjan has now been repaired, it is possible to add a few more details concerning the Erzinjan earthquake of December 27, 1939 (see NATURE of Jan. 6, p. 13). From Ankara to Sivas and Tokat the damage has been done chiefly to the old and badly constructed buildings made from inferior material, whilst the better ferro-concrete public buildings of recent construction have escaped with cracks and minor damage; but from Tokat and Sivas to Erzinjan there has been practically complete destruction of old and new. The only 'oasis' of lesser damage thus far recorded has been at Kemah near Erzinjan, where some buildings still stand, though 548 buildings were wrecked and nearly 150 casualties caused. It appears probable that Kemah was built on more solid rock than the other towns in the area of approximately 15,000 square miles affected.

In the mountainous district between Amasya and Tokat there are ground fissures 12 yards wide, out of which are said to issue smoke and sulphur fumes and also jets of boiling water. There is as yet no direct news of some five hundred villages to the east of Erzinjan, although efforts are being made to reach them through a countryside covered to a depth of 12 ft. in snow. At Niksar, a rock pinnacle fell on the town, doing much damage, and there were few survivors in this place or in fourteen of the neighbouring villages, whilst on the Black Sea coast the towns of Kerasun and Ordu are reported to have suffered the greatest damage.

At Kew Observatory the first waves to arrive did so at 0h. 3m. 26s. G.M.T. and the maxima exceeded the limits of registration, the ground movement being greater than one millimeter in amplitude. Several severe after-shocks have occurred as well as hundreds of smaller ones. On January 1 there were seven severe after-shocks at Erzinjan, and a violent shock at 7 a.m. local time at Bergama in the west of Turkey. On January 2 at Yozgad there was a strong shock and 190 houses collapsed, though no casualties are reported. The after-shocks appear now to be decreasing in strength and number. Although the after-shock of January 1 was at Bergama, it is yet uncertain whether the floods in the Brusa and Smyrna districts of Turkey and in the Bilecik Valley (River Sakaria) had anything to do with changes in topography attendant on the earthquakes, nor whether the Kemal Pasha Dams and numerous river bridges were destroyed by the shocks or by the floodwaters, but if the meteorological conditions in the area did not cause the floods, they certainly enhanced them considerably.

Other Recent Earthquakes

ON December 21, San José (Costa Rica) suffered the most severe earthquake it has known since 1923. Buildings were cracked, including the cathedral, though no casualties are reported. The shock was recorded at Manila, at De Bilt (Holland), where the *P* wave arrived at 21h. 7m. 10s. G.M.T., and at Kew, where the first of three shocks in rapid succession arrived at 21h. 6m. 51s. G.M.T., the maximum ground amplitude at Kew being 0·42 mm. On December 22, considerable damage is reported to have been caused by earthquake shocks in Costa Rica, though no loss of life or other casualties are reported. These shocks were possibly after-shocks of the earthquake which rocked San José on December 21.

On December 22 also severe earthquake shocks were experienced in the South Sea islands of Molucca. On December 23 and 24 earthquakes and landslides, which were probably caused by the earthquakes, occurred in Java in the East Indies. In addition to the Anatolian earthquake of December 27, further shocks were registered at Kew Observatory on December 25 (2), December 28 and December 29. Further news concerning all these shocks is awaited from the areas concerned and from other seismological observatories. On January 2, early in the day, an earthquake shock was perceptible on the Ionian Island of Zante (Greece), though no damage or loss of life has been reported.

Potatoes in War-time

POTATOES are one of the most valuable sources of human and animal food in war-time, and it is of the greatest national importance that both the acreage devoted to this crop shall be increased and that the maximum yields shall be obtained. Questions of quality, colour and shape must now take second place and yield be the all-important aim of the grower. The National Institute of Agricultural Botany, Cambridge, has just issued a war-time edition of its Farmer's Leaflet No. 3, in which useful information to this end is supplied. Emphasis is laid on the necessity for using healthy seed, as otherwise attention to cultivation, manuring, etc., is of little value. A number of varieties are recommended for both early and main crops; but it is pointed out that to lift potatoes in an unripe condition is an unwarranted waste of tonnage in a time of emergency. As regards choice of varieties, most of those commonly grown are still recommended, but King Edward should be replaced by a heavier cropping kind such as Arran Banner, Arran Consul, Kerr's Pink, Majestic or Redskin.

The use of unsaleable potatoes for animal feeding is the subject of "Growmore" Leaflet No. 10, issued by the Ministry of Agriculture. All potatoes, whether to be used raw or cooked, should be washed before feeding, or digestive trouble may result. Raw potatoes can be used safely in moderation for cattle, dairy cows and sheep; but they are not suitable for young stock, horses or pigs. Cooked potatoes, however, can be successfully fed to pigs of all ages, and a table of suitable quantities is provided. Potato and potato and green fodder silage are other useful ways of utilizing waste tubers, particularly if some of them are slightly diseased, and simple methods for preserving them in this way are described. Nutritious food of a feeding value equivalent to about a quarter of its weight of barley meal, and suitable for sheep, cattle and pigs, can thus be produced.

Johann Friedrich Blumenbach (1752-1840)

JOHANN FRIEDRICH BLUMENBACH, a pioneer in anthropology and craniology, was born on May 11, 1752, at Gotha. He studied medicine at Jena under Soemmering and qualified in 1776 at Göttingen, where he was appointed extraordinary professor of the practice of medicine in the following year and full professor in 1778. In his thesis entitled "De generis humani varietate nativa" (1776), which according to Garrison is the starting point of modern ethnology, he based his classification of mankind upon the shape of the skull and the facial configuration as well as on the colour of the skin. As the result of his craniological investigations, he divided the human race into five great families: the Caucasian or white race, the Mongolian or yellow, the Malayan or brown, the Negro or black, and the American or red.

Blumenbach was a voluminous writer. His principal work, which was published in 1790–1820, was entitled "Decades 1–6 collectiones suae craniorum diversarum gentium illustratæ". He was also the author of "Handbuch der Naturgeschichte" (1779–80), "Ueber der Bildungstrieb und das Zeugungsgeschäft" (1781), "Institutiones physiologicæ" (1787), "Beiträge zur Naturgeschichte" (1790–1811), and "Handbuch der vergleichenden Anatomie" (1805). He was also the editor of "Medicinische Bibliothek" from 1785 until 1795, and contributed many articles to periodical literature. He was a fellow of the Royal Society, member of the Royal Academy of Sciences of Paris, and the recipient of many other honours at home and abroad. He died on January 18, 1840.

Neanderthal Man in Central Asia

A PRELIMINARY account of the discovery of skeletal remains of Neanderthal man in Central Asia is given by Dr. Aleš Hrdlička through the Smithsonian Institution of Washington. The remains—the skull of a child, with the lower jaw and all the teeth, and some of the bones of the skeleton in a fragmentary state—were found by Dr. A. Nokladnikov in a cave of the Gissar Mountains of Siberia. The discovery is of special importance, as not only is this the first example of Neanderthal man to be recorded from Central Asia, but it is also the farthest extension of the type eastward hitherto known. With the exception of the finds in Palestine, all previous specimens have been found in Europe. Dr. Hrdlička, who has had an opportunity of examining the material while on a visit to Siberia recently, regards it as one of the most important discoveries in anthropology of the last two decades, and further as lending support to his view that there is an overlap in skull pattern between Sinanthropus and Neanderthal man.

In an account of the find which Dr. Hrdlička received at first hand from those who were responsible for the discovery, it was stated that the cave deposits contained many splintered bones of deer, leopards, wild horses, goats, boars, marmots and birds. Many of these showed evidence of having been used in the manufacture of stone implements. Most of these implements were made of local limestone, but the finest were of jasper. Good material for implement-making, however, was scarce. Typical Mousterian scrapers and small pointed implements, chipped on one side, were associated with the animal bones, and both were in relation to fire-places. The human skeletal remains were imbedded in a sterile underlying stratum. An interesting feature of their disposal was that they were encircled by five pairs of goat horns, of which three were still united.

Psychology of the Initiate

An interesting sidelight is thrown on certain changes in mentality taking place after initiation by an examination of two series of drawings made by an Australian aboriginal boy, which have been recorded and reproduced by C. P. Mountford, acting ethnologist of the South Australian Museum (*Records S. Austral. Mus.*, 6, 2; 1939). The subject was one of two interpreters accompanying an anthropological expedition of the University of Adelaide to the Warburton Ranges of Western Australia in 1935. At the time of his engagement it was understood that he was a full initiate; but when an investigation of aboriginal art was being made, it was noted that when drawings of a secret character were being made by tribesmen, they were carefully concealed on his approach. His own drawings in the first series invariably represented objects of, or known to, European civilization.

This fact, coupled with his failure as an interpreter, led to inquiry, when it was found that initiation of the man had not been completed. Though circumcized, he had not been subincized, and consequently in all matters affecting tribal ritual he was virtually ostracized, while his behaviour consorted with that of younger members of the tribe. Full initiation, which was then carried out, induced a remarkable change in his outlook, behaviour, and what from one point of view was of greater moment, in the attitude of other members of the group. The youth assumed the attitude and behaviour of a senior of the tribe; he was no longer prevented from seeing ceremonial drawings and taking part in ritualistic discussions, while, it is interesting to note, his own drawings now depicted the ceremonial designs associated with, or recording tribal traditions. The author's comment is significant. He points out how any interference with tribal ritual by outside influence may prove an effectual bar to association with tribal society, while still not securing an admission to any real participation in white civilization. The lesson is instructive.

Supposed Risso's Grampus in the Mersey

THE importance that authorities in tidal districts be acquainted with the fact that, under an arrangement made some few years ago, all large cetaceans stranded on the shores of Great Britain should be offered to the British Museum before any decision is made to dispose of them, is well borne out by the unfortunate destruction of a rare cetacean recently stranded in the Mersey. The flood tide of December 10, stranded a large cetacean in the Mersey at Widnes, and various unofficial reports circulated suggested it to be a porpoise, dolphin, or killer whale. Immediately upon discovering that no local museum or university had been informed of the rarity, the Merseyside Naturalists' Association went to considerable trouble to collect all available evidence and photographs and to interview all people who had handled the specimen. Through some misunderstanding, it appears that although the customs authorities had told the transporter company who recovered the whale that any scientifically interested body could have it, the Upper Mersey Conservators took possession of the carcass the day following its stranding, cut it up into pieces and returned it to the river from one of their vessels.

Evidence which was gathered by the Merseyside Naturalists' Association strongly suggests that the animal was a Risso's grampus (*Grampus griseus*), of which there is no previous Lancashire or Cheshire record. The report of evidence it collected gives: Length, 11 ft. 2 in.; upper parts: dark grey, almost black, blotched and streaked plainly with greyish-white, dorsal fin broad and high; head: no teeth in upper jaw; lower jaw with a few rather blunt teeth spaced about 0·75 in. apart; lower jaw a shade shorter than upper jaw; whitish tinge to muzzle and greyish tinge to head; head large and swollen like that of pilot whale; underparts white, smooth; flippers long, narrow and pointed; tail flukes narrow. No scientific measurements had been taken owing to the surprising and unannounced destruction of the carcass, but a photograph taken by a local man had been secured. The specimen was still alive and blowing when stranded and roped.

The Meteorological Office

THE recently issued report of the Director of the Meteorological Office for the year ending March 31, 1939 (H.M. Stationery Office. 9*d*. net), is largely occupied with a description of changes of organization arising from the rapid expansion of the Office, due mainly to the expansion of the Royal Air Force; it contains also an account of the methods adopted for dealing with routine requirements of the different services and of civil aviation. For these reasons a more careful perusal of the report is necessary than has generally been the case in the past in order to find items of purely scientific interest, although, it is curious to note, the decision was made during the period under review, to make organized research a part of the normal work of the Office, instead of leaving research to individual enterprise on the part of the scientific staff.

The most important instrumental problem that has been pursued has been the development of the *radio-sonde* method of measuring the pressure, temperature and humidity of the atmosphere up to heights of 10 miles or more. The apparatus arrived at has been developed in collaboration with the National Physical Laboratory. It is carried by a free balloon, and transmits radio signals which are modulated in a manner dependent on the physical state of the atmosphere with which the balloon is surrounded at the moment. Fifty ascents were made, in most of which a Dines meteorograph was attached so that a check on the indications of the radio transmitter was available eventually on those occasions when the instruments were recovered. Much time was spent in trying to eliminate various sources of error that were encountered. Trials of a radio method of measurement of winds at great heights were continued, the method consisting of observations by two distant radio direction finding stations of the position of a small radio transmitter carried by a balloon. The main difficulty arose from the deflection of the radio signals by surface objects, which necessitated elaborate calibration. During the year under review the use of the cloud searchlight for rapid determination of cloud height at night was greatly extended. Improved specifications for pilot balloons were considered, with the view of avoiding the rapid deterioration experienced in hot climates, also improved methods of storage.

Terminal Velocities

DR. HERBERT CHATLEY prepared a paper on 'terminal velocities' for delivery to the Junior Institution of Engineers on October 13. It is now published in the December issue of the *Journal* of the Institution. In many engineering and physical problems of the present day, the question often arises as to the maximum velocity developed when a body falls in a fluid medium. To give a rough idea of the terminal velocities, Dr. Chatley compares the impact velocity of a stream-lined aerial bomb and the speed with which the finest clay suspensions settle in water. Between these speeds he considers the landing speed of parachutes, the fall of rain or oil-drops, the vertical current speeds necessary in coal dust or grain elevators, the suspension of sand or silt in rivers, and the settlement of dust particles in a room.

When an elevated body is released, it falls earthwards according to the law of gravitation. As it proceeds, the resistance of the air or water increases up to a definite value, namely, when this resistance equals the weight of the body. When this happens, the velocity remains constant and is called the terminal velocity. A sand particle one micron in diameter has a terminal velocity in water of about 0·001 mm. per second; in air it is about ninety times as great. One of the most useful applications of the terminal velocity is in the computation of the power required to sustain bodies when placed in a current of fluid. For example, in the elevation of grain from a hopper or ship's hold to a level somewhat above the receiver, out of which it flows to a second container (say, 50 feet lift), modern plants consume about 0·8 h.p. hour per ton. This represents a very low efficiency. In a vertical pipe a fluid ascends more quickly than a suspended material, their relative velocity being the 'terminal velocity' in this case.

A Zinc 'Famine'

ACCORDING to the *Electrical Contractor and Retailer* an idea was current a short time ago that a shortage of zinc was responsible for the recent famine in torch-batteries. This is not the case as there was plenty of zinc in Great Britain and the torch-battery famine was due entirely to the overwhelming Government and public demand for these accessories—and quite naturally so. When a large number of people suddenly resolve to carry flash-lamps, something like a temporary famine is unavoidable. During the life of an ordinary dry battery possibly five per cent of the zinc is consumed and so about 95 per cent of the zinc used for this service is thrown away. It looks as if we were surrounded by an appalling waste in various directions. Notice, for example, the packing of tobacco and cigarettes for domestic use in 'tins' and then visualize the waste of iron and tin thereby involved. Many of these tins are also provided with substantial rubber seals, all of which are used once and then thrown away. It would be of interest if somebody considered whether this waste is serious or not, and if it is, then investigate how the saving could be effected.

Training Physicists

DURING the last six years there has been much discussion in the United States as to the most suitable training for physicists who are required in industry, and the conclusions come to have been summarized in these columns. In general, the training then available was considered to provide a superficial acquaintance with the latest developments of quantum theory and of atomic disintegration rather than a fundamental knowledge of the older physics. Criticisms of the same type were made in the May issue of *Metals and Alloys* this year and were quoted in the July issue of the *Journal of Scientific Instruments.*

In the November issue of the *Journal,* two physicists in the research department of a cable works in Great Britain point out that the criticism applies equally well to the training the universities of Great Britain provide, and that in consequence industrialists are reluctant to employ physicists. They think that the position would be improved if the universities provided some training in applied physics and supplemented it by visits to works and by practical experience in works during vacations.

Fused All-Glass Cells

MESSRS. TINTOMETER LTD., of Salisbury, announce the manufacture of a range of fused all-glass cells suitable for holding liquids for colorimetry, photometry, polarimetry and other purposes. The construction of the standard type consists of a body of a single bend of glass with faces of clear glass sintered to it. This avoids the use of the usual cements, which often break down under the attack of alkalis and other solvents. It is claimed that the accuracy of the thickness is within ± 4 × 10^{-3} in. for cells of one inch or less ; moreover, examination shows that distortion of the faces in the sintering process has been very largely avoided. Beside the standard types, hollow cubes, prisms, rectangular cells, double light-filter cells, and 'blood' cells are also being manufactured. It appears that these products will form a useful addition to the range of such articles manufactured in Great Britain.

Rhodes Scholars

THE "Statement of the Rhodes Scholarships" for the academic year 1938–39 shows that 68 scholars began their English experience, while 188 were in residence. Among the subjects covered, natural science and medicine with 45 representatives, and jurisprudence and the Modern Greats school with 38 each are easily the most popular. Agriculture, forestry and music have solitary devotees. The record is good on the whole in academic distinctions, and includes several names well known in sport and athletics. The list of books published by men of the foundation is long. The Rhodes scholars include a dean of Christ Church and a regius professor of medicine. They come to England with previous academic training and at an age more advanced than that of the average undergraduate. The question whether this discrepancy is advisable has been the subject of considerable comment.

Scientific Research in India

THE progress of research in India can be followed by the help of the *Indian Science Abstracts,* which is an annotated bibliography arranged by subjects. Some of these bear closely on the economic development of the country, and their principal interest is local rather than general. Part 1 for the year 1937 covers mathematics, physics, geology and botany (National Institute of Sciences of India, September 1939). Mathematics has 86 papers, five of which deal with Indian geodesical problems, physics has 189, only a dozen of which deal with local meteorological or geophysical subjects; geology has 316 and botany 286, dealing almost exclusively with Indian problems.

Alchemical Manuscripts

VOLUME 6 of *Osiris,* dedicated to Prof. Bidez, contains his portrait and a bibliography of his publications. The rest of the volume of 844 pages consists of a "Catalogue of Latin and Vernacular Alchemical Manuscripts in the United States and Canada" by W. J. Wilson, of the Library of Congress, Washington. After a brief but very interesting general introduction, the text consists of detailed and annotated analyses of 79 manuscripts, with 41 facsimile figures. The dates of the manuscripts range from the thirteenth to the nineteenth centuries. Many of them contain collections of recipes. There is a very full index (pages 690–844). The work is thorough and reaches a high standard of scholarship it is a notable addition to the literature of a subject which has recently attracted a good deal of attention, namely, the history of alchemy.

Early Works on Medicine and Science

WE have received from Messrs. Goldschmidt and Co., Ltd., 45 Old Bond Street, W.1, their Catalogue No. 53 listing rare early works on medicine and science. Pride of place is occupied by a good and large copy in vellum of the first edition of William Harvey's "De Motu Cordis" (1628), and also a copy of the rare third edition of the same work. A complete set of Conrad Gesner's "Natural History" (1551), three of Kepler's important works, a work by Joseph Black on alkalis (1770) and William Withering's "An Account of the Foxglove" are also to be noted. A number of less rare though none the less important books and tracts by Erasmus Darwin, Euler, Faraday, Fayrer, Fraunhofer, Stephen Hales, Mendeléeff, Pasteur, Lister, Fox Talbot and many others are also listed.

Medical and Scientific Lending Library

PART 2 of the new edition of the "Catalogue of Lewis's Medical and Scientific Lending Library", revised to the end of 1937, has now been issued (London: H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1. 16*s.* net; to subscribers, 8*s.*). It contains the classified index of the subject-matter of the books, with the names of their authors, upon medical and scientific subjects contained in Lewis's Library. An extensive subject is subdivided to facilitate reference; for example, chemistry has eleven, and agriculture thirteen, sub-headings. The date of publication is given, and a note is frequently added to indicate the scope of the work. It will be appreciated what a large number of works is listed when it is mentioned that the text occupies 156 pages, each with three columns and each column containing authors' names of some 30–45 works. The catalogue should therefore prove a very useful general guide to medical and scientific books.

Big Sunspots

A BIG group of sunspots, originating about January 1 and growing rapidly, crossed the sun's central meridian on January 5 and reached the west limb on January 12. Between January 2 and 4, the area increased tenfold and measured 1,300 millionths of the sun's hemisphere on the latter date. Still expanding on January 5, the spots were clearly seen with the naked eye through the morning mist. In structure, the group was a typical stream with leader and follower spots and subsidiary spots in between. This group is the largest since last September, and indicates that, although the maximum of the 11-year cycle is past, the sun is still generally active.

Royal Institution Discourses

THE following Friday Evening Discourses have been arranged by the Royal Institution to be delivered before Easter. The discourses begin at 5 o'clock: January 19, Sir Leonard Woolley, "The Latest Excavations at Atchana in North Syria"; January 26, Sir Noel Ashbridge, "Long Distance Broadcasting"; February 9, Prof. L. C. Martin, "Ultra-Violet and Electron Microscopy"; February 16, Sir William Bragg, "Physics in War-time"; March 1, Lord Eustace Percy, "Peace-making after War: Past History and Future Problems"; March 8, Sir William Bragg, "Experiments from the Researches of Sir James Dewar"; March 15, Sir Frederick Keeble, "Agriculture and National Well-being".

Announcements

THE Harrison Lectureship Medal of the Pharmaceutical Society will be awarded to Mr. A. D. Powell at a meeting on January 9 at 7.30, when Mr. Powell will deliver the Harrison Memorial Lecture entitled "Drug Standards: their Development and Application".

THE next monthly meeting of the British Institute of Radiology will be held in the Reid-Knox Hall on January 19, at 2 p.m., when the following lectures will be delivered: Silvanus Thompson Memorial Lecture entitled "The Irradiation of Liquids", by Prof. F. L. Hopwood; Mackenzie Davidson Memorial Lecture entitled "Maternal Mortality and Radiology", by Dr. L. A. Rowden.

THE Friends of the National Libraries decided at their annual meeting to continue their activities during the War. Acquisitions during the year included a number of early and rare books on science presented to the Science Library at South Kensington, a volume of drawings by the architect, Edward Blore, of country houses and other buildings, given to the Royal Institute of British Architects, and the purchase of a collection of papers belonging to the publishing business of Robert Cadell, Stoneham and Houlston.

THE Paris Academy of Medicine has awarded the Jansen Prize to Prof. A. Bessemans, pro-rector of the University of Ghent, for his work on spirochætes.

THE Albert Brachet Prize of 12,000 francs is awarded every three years for the best work on embryology published during this period in English, French, Dutch, German or Italian. Further information can be obtained from the Secrétarie perpétuel de l'Académie Royale des Sciences, des Lettres et des Beaux Arts de Belgique, Palais des Académies, Brussels.

THE Emergency Executive Committee of the International Congress of Mathematicians has decided definitely to postpone until some more favourable date the Congress which was to have been held in Cambridge in September 1940.

A EURASIAN YOUTH MOVEMENT has been launched in Singapore with a scheme to uphold and improve the social, moral, physical and intellectual welfare of the Eurasian youth when they leave school.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 73. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Anisotropy of Cellulose Sheet

IN view of the results just published by Spence[1] on the optical anisotropy of films prepared from various esterified celluloses, it may be of interest to record some recent measurements on 'Cellophane' (regenerated cellulose) sheet.

This material is observed to be optically bi-axial, the axes lying in the plane defined by the direction of extrusion and the normal to the sheet. The measurements made in this laboratory are not, as in Spence's case, direct measurements of birefringence, but are observations of the two principal refractive indexes in the plane of the sheet, and of the optic axial angle. From these the refractive index normal to the sheet and the birefringence have been calculated. Numerical results for two batches of material are given in the accompanying table, where θ is the angle between one optic axis and the normal to the sheet; n_γ is refractive index for electric vector along extrusion direction; n_β is refractive index for electric vector in plane of sheet at right angles to extrusion direction; and n_α is refractive index for electric vector along normal to sheet.

		θ	n_γ (obs.)	n_β (obs.)	n_α (calc.)	$(n_\alpha - n_\gamma) \times 10^5$
Acid and water-washed sheet	Wetted	43·0°	1·413	1·408	1·403	−1000
	Air-dry	45·7°	1·534	1·526	1·519	−1500
Sheet undried during manufacture	Wet	56·5°	1·382	1·377	1·374	− 800
	Freely dried	57·6°	1·531	1·521	1·517	−1400
	Stretched and dried	72·3°	1·535	1·521	1·520	−1500

For ready comparison with Spence's birefringence figures, the values for $(n_\alpha - n_\gamma)$ are given in the same units as used by him although, owing to the method by which the figures were obtained, they cannot have the same accuracy as his. They are not inconsistent, however, with the values to be expected—by extrapolation to zero acetyl content—from Spence's figures obtained on sheets prepared from cellulose acetylated to different extents.

It may be observed that, while the 'slow ray direction' and the direction of extrusion or stress are coincident in the regenerated cellulose sheet, Spence found them (with one exception) to be at right angles in sheets made from cellulose esters with various acyl groups. Moreover, in cellulose sheet, increase of the stress along the direction of extrusion leads to increase in the negative value of $(n_\alpha - n_\gamma)$, in contrast again to the behaviour of the esters.

These differences are probably to be ascribed to the absence of acyl side chains in regenerated cellulose, since any 'selective' orientation that may be induced by stress will presumably have less effect on n_α and n_β in cellulose than in its esters. The values of n_α and n_γ in the material examined are nevertheless both increased by stress, while n_β remains remarkably constant.

Heat Conductivity of Rubber at Low Temperatures

WHILST examining the possibilities of applying rubber in low-temperature work, we were hampered by the lack of available data of its physical properties at low temperatures. We were quite aware of the difficulties to be expected in making accurate measurements in that temperature region, and this applies specially to the heat conductivity in which we were particularly interested. In order to obtain at least an estimate of the order of magnitude, we carried out some measurements of the heat conductivity of commercial rubber (tyre rubber, North British) at room temperature and the temperature of liquid air.

We used (1) the standard method (heat transmission through a thin sheet) at both temperatures with a small vacuum apparatus which had a circular cross-section of about 7 cm.^{2}; the specimen had a thickness of 0·9 mm.; (2) we checked the low-temperature measurement by the following method: a bag of the same rubber was immersed in liquid oxygen and filled with liquid nitrogen. The rate of evaporation of the nitrogen was measured and, together with the dimensions of the bag, allowed of an independent determination of the heat conductivity. The mean values obtained by both methods are as follow:

T	293°K.	83°K.
cal./sec.cm.°K.	0·00055	(1) 0·000018
		(2) 0·000010

This considerable drop in the heat conductivity to, say, one fortieth from room to liquid air temperature does not seem to be confined to this particular rubber, as other specimens which we subjected to rough measurements show a similar behaviour.

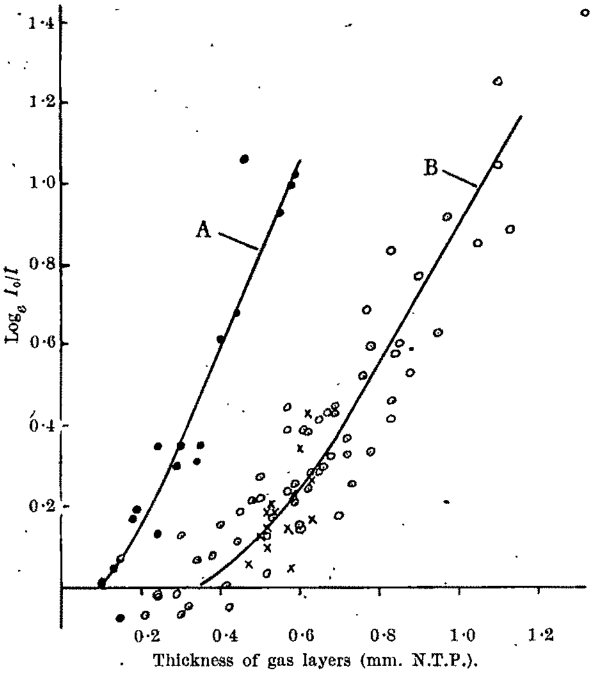
Absorption of Hydrogen Lyman Radiation by Atmospheric Gases

THE absorption of the hydrogen resonance line at 1215·7 A. has been investigated to obtain more exact information bearing on the theory of the production of short-wave radio fadeouts by solar eruptions[1]. The following results have been obtained:

(1) Nitrogen is transparent in layers up to 3·2 mm. thick (N.T.P.), in agreement with the early observations of Hopfield[2] and more recent measurements by Preston[3].

(2) Exact measurements on water vapour were difficult, but more than half the incident radiation is absorbed in a layer about 0·05 mm. thick. This agrees with Preston's observations.



●, oxygen; ⊙, air (energy in disruptive charge, 6 watts); ×, air (energy in disruptive charge, 3 watts).

(3) The absorption in oxygen and air was found to be much heavier than was expected from previous work. In the region where absorption commences, the densities of the parts of the hydrogen line in the absorption spectrum and the check spectrum without absorber, which was put on the same film, were compared directly as an approximate measure of the absorption. Lack of the characteristic curves for the emulsion should not cause serious errors in the comparison of nearly equal densities.

In the accompanying figure, Curve A shows the absorption of molecular oxygen in layers up to 0·6 mm. thick (N.T.P.). The ordinates are $\log_e I_0/I$ (I_0 being the unabsorbed and I the absorbed intensity); in the usual formula for mass absorption, $\log_e I_0/I = \mu x + c$. Since absorption appears to start only when there is a minimum gas layer amounting to about 0·10 mm., then c is not, in this case, zero. In addition, the absorption coefficient, μ, may not be constant for small values of the absorption.

Curve B shows the absorption in air. Several points falling below the axis of zero absorption indicate the possible magnitude of individual errors, and the general scatter of observations makes it difficult to define the absorption curve accurately. Its slope, however, is not constant, and again, there is no absorption until a minimum layer of gas is present. This minimum appears to be between 0·30 and 0·40 mm. (N.T.P.) and is not exactly five times the minimum in oxygen. For the strong bands at 1140, 1245 and 1450 A. absorption is clearly apparent in the least amounts of gas used for observations on 1215·7A.

The absorption coefficients given for oxygen and air by Preston are about fifty times less. In the present case the absorbing gases were pure to within three parts in a thousand, and, in addition, water vapour, the most powerful absorber, was ruled out as an unobserved impurity by check experiments with saturated nitrogen. It is possible that Preston's observations were in error owing to serious dissociation of the oxygen in his apparatus (cf. the difficulties experienced by Ladenburg and van Voorhis[4]). In the present case reduction to half the energy dissipated in the discharge caused no observable difference in the absorption measurements, showing that dissociation of the oxygen was negligible.

With a fixed absorption path the pressure is varied in order to change the thickness of the absorbing layer, and it would appear from the two curves, therefore, that the partial pressure of the oxygen in the spectrograph is the factor determining the onset of absorption. This minimum pressure is about 0·04 mm. If absorption of 1215·7 A. is only possible when an oxygen molecule is in a slightly perturbed state owing to its collision with another oxygen molecule, the absorption coefficient should vary as the square of the pressure until the population density of absorbing molecules is constant. In oxygen at very high pressures, Shalow and Steiner[5] have found absorption bands which behave in this way, and attributed by them to the temporary formation of O_2–O_2 molecules.

If λ 1215·7 is emitted from the sun, no absorption will take place until it reaches levels in the upper atmosphere where the partial pressure of molecular oxygen is about 0·04 mm. (about 80 km.), except for attenuation due to the small amount of water-vapour above this height. According to the shape of the 'tail' of the absorption curve, the radiation would be absorbed more or less rapidly in dissociating oxygen molecules and producing ionization according to the process previously suggested[1]. The resultant ionized layer would perhaps correspond to that found by Budden, Ratcliffe and Wilkes[6].

This work has been made possible through a grant for research made by the Commonwealth Government.

Does the Mesotron Obey Bose-Einstein or Fermi-Dirac Statistics?

WHETHER the mesotron obeys Bose-Einstein or Fermi-Dirac statistics is closely associated with what one assumes regarding the nature of the field, emission and absorption of which by the heavy particle is responsible for the interaction between elementary nuclear particles. If the field be a one-particle field, as postulated by Yukawa[1], the mesotron obeys Bose-Einstein statistics, and has a spin equal to unity (All momenta are expressed in units of $\hbar$.) However, in view of the fact that all known elementary particles obey Fermi-Dirac statistics and possess a spin $\frac{1}{2}$, one is rather reluctant to accept, unless experimental evidence points that way, that the mesotron obeys Bose-Einstein statistics and has a spin equal to unity. If we could suppose that the field involved is a two-particle field instead of a one-particle one, Fermi-Dirac statistics and a spin of $\frac{1}{2}$ could be attributed to the particle concerned. So we suppose that the mesotron is emitted or absorbed by a heavy particle always in conjunction with a neutrino or an antineutrino. In symbols

$$\begin{aligned} P &\rightleftarrows N + \eta^{+} + n^{-} \\ N &\rightleftarrows P + \eta^{-} + n^{+} \end{aligned} \qquad (1)$$

where N and P stand for a neutron and a proton respectively, n^{-}, n^{+} for a neutrino and an antineutrino, and η^{-}, η^{+} for the negative and the positive mesotron, which now obey Fermi-Dirac statistics and possess a spin of $\frac{1}{2}$.

If we start with a neutron and a proton at $\vec{r}_1$ and $\vec{r}_2$ respectively, processes (1) obviously lead in the second approximation of the perturbation theory to an exchange interaction between the nuclear particles. If we suppose that the spin of the heavy particle is not affected during (1), the exchange force is purely a Heisenberg force; if, on the other hand, the spin of the heavy particle is reversed during (1), we get a purely Majorana force, so that the correct spin dependence of nuclear forces is obtained by choosing for the interaction between the heavy particles and the mesotron-neutrino field a form which combines the above two.

The forces between like particles, which are known[2] to be of the same order of magnitude, for anti-parallel spins at least, as the force between unlike particles, can likewise be explained by introducing the neutral counterpart of the mesotron.

The phenomenon of β-decay can be fitted into this theory if it is assumed that the mesotron disintegrates into a β-particle and a γ quantum; so that the emission of a β-decay particle during a β-decay is accompanied not by a neutrino alone, as on Fermi's theory, but also by a γ quantum. This departure from Fermi's theory should enable us to explain in a more satisfactory way the energy distribution curve for the β-particle transformation.

Detailed calculations will be published elsewhere.

Interpretation of Nebular Red-Shifts

IN a recent communication[1], M. E. J. Gheury de Bray discusses the possibility of explaining the red-shifts by assuming that the velocity of light (c_T) is constant throughout the universe at any given time but decreases with time (T).

This hypothesis implies the assumption (*a*) that the atomic frequencies remain constant throughout space and time and may therefore be used as clocks (atomic clock '*AC*') for time measurements; (*b*) that measuring rods, other than light years (which contract with a decrease of c_T), can be found. For such measuring rods we may now choose the distances of *the material points* (for example, the nebulæ) in the universe, as according to the hypothesis the universe neither expands nor contracts. Such measuring rods we call 'material rods' ('*MR*').

It shall be shown here that the proffered hypothesis, based on the measuring system $AC + MR$, is one of three alternative ways of formulating the hypothesis of the expanding universe.

The following clocks and measuring rods can be taken as basis of a measuring system for cosmological purposes:

(*a*) Clocks	(*b*) Measuring rods
AC (atomic clocks); *or*	*MR* (material rods); *or*
LC (light-clocks: the time taken by light over a given distance—*c* is here assumed as constant).	*LR* (light-rods, for example, light years: the distance covered by light in a given time—*c* is here assumed as constant).

Only the following three combinations of these clocks and measuring rods can be taken as basis of a measuring system: $AC + MR$, which is the basis of Mr. Gheury de Bray's hypothesis; $AC + LR$, a basis which leads to the expansion theory of the red-shifts, and $LC + MR$, which leads to what Milne[2] calls 'dynamical time scale', and to the 'speeding up' theory of the red-shifts.

($AC + LR$). The theory of the expanding universe states that the distances between material points, measured in *LR*, increase; in other words, it maintains an increase of *MR* against *LR*. This leads to the recession of distant nebulæ and to the Doppler effect. The identity of the frequencies of characteristic spectral lines throughout the universe (atomic clocks) is thereby assumed; the measuring system of the theory is thus the $AC + LR$-system. In tracing back the recessive movements it is found that $1{\cdot}86 \times 10^9$ years ago the size of the universe was zero. Thus an absolute scale of time T (based on the atomic clock) is assumed in which the unit is the (atomic) year and the *present value* of T is $T_P = 1{\cdot}86 \times 10^9$. (This 'age of the world' is confirmed by other measurements based on atomic radioactivity clocks.)

($AC + MR$). The above statement that *MR* increases if measured in *LR* is equivalent to saying that *LR* decreases if measured in *MR*. If *MR* is chosen and the clocks are not changed, the system $AC + MR$ is adopted. The decrease of *LR* means a decrease of the velocity of light (measured in *MR*). This permits an explanation of the red-shift of old light, since c_T was greater at the time $T - \Delta T$ when it was emitted and therefore $\lambda_{T-\Delta T}$ is longer than λ_T.

($LC + MR$). There is a third way to express the same facts. If we allow the light a longer time for its voyage, by defining our clocks in such a manner that they are slowing down as compared with the atomic clocks, then the decrease of c can be made to disappear. In other words, we adopt a new time scale τ in which the atomic frequencies throughout the universe are speeding up; this explains the red-shift of old light.

The three alternative ways of expressing things agree in regard to the observable effects they describe. All predict the red-shift of old (distant) light. All therefore also predict a violet shift of characteristic spectral lines in the course of time to come (in $AC + LR$, that is, in the expansion theory, this has to be explained by an expansion of the spectroscope's grating). The three theories are logically equivalent, and therefore do not describe alternative *facts*, but the same facts in alternative *languages*. (To ask whether 'in reality' the universe expands, or c decreases, or the frequencies speed up, is not more legitimate than, when prices of goods fall throughout the economic system, to ask whether 'in reality' the value of money has increased or the value of the goods has decreased.) Nevertheless, the $AC + MR$-language seems to offer a particularly simple mathematical treatment and, furthermore, an *observational approach* to Milne's 'dynamical' time scale. It shall therefore be briefly examined.

In $AC + MR$, where characteristic atomic frequencies are assumed constant and c_T depends in some way upon T,

$$(1) \qquad (d\lambda/\lambda)_{T+\Delta T} = (\Delta c_T/T)_{T+\Delta T};$$

on the other hand, the observational law of red-shifts (velocity-distance relation) can be written:

$$(2) \qquad (d\lambda/\lambda)_{T_P-\Delta T} = (\Delta T/T)_P,$$

if the 'apparent distance' in light years, calculated on observed luminosities, is identified with ΔT. From (1) and (2) we get

$$(3) \qquad (\Delta c_T/\Delta T)_P = (dc_T/dT)_P = -(c_T/T)_P.$$

Generalizing this and integrating we get the law of the decrease of c:

$$(4) \qquad c_T = c_P T_P/T.$$

If we proceed from $AC + MR$ to $LC + MR$, we have to introduce a time scale τ so that $c_\tau = c_P =$ constant. In order to get the general formula for $d\tau/dT$, we make use of (4), which can now be written as

$$(5) \qquad d\tau/dT = c_T/c_\tau = c_T/c_P = T_P/T;$$

integrating and choosing $\tau_P = 0$ (Milne chooses $\tau_P = T_P$), we arrive at

$$(6) \qquad \tau = T_P \log(T_\tau/T_P),$$

which is essentially Milne's formula (A)[2]; the index 'τ' in 'T_τ' indicates the value of T at the instant τ of the τ-scale. Equivalent to (6) is $T_\tau = T_P e^{\tau/T_P}$. From this and (5) we get the law of the 'speeding up' of characteristic frequencies when measured in $LC + MR$, that is, on the τ-scale:

$$(7) \qquad \nu_\tau = \nu_P dT_\tau/d\tau = \nu_P e^{\tau/T_P},$$

and from this and $c_\tau = c_P$ we get, corresponding to (2), the law of red and violet shifts in the form

$$(8) \qquad (d\lambda/\lambda)_{\tau+\Delta\tau} = -\Delta e^{\tau/T_P}/e^{\tau/T_P} = -\Delta T_\tau/T_\tau.$$

In the above deduction we have identified the 'apparent distance' (calculated on observed luminosities, that is, energy densities ρ, and not corrected for departures) with ΔT. Thus our assumption regarding ρ is that it measures the square of the *time* ΔT the light travels, which in $AC + MR$ cannot be identified with the ('real') *distance* r; for as the light was quicker when it was emitted, $r > \Delta T$. If the usual assumption that ρ measures not $(\Delta T)^2$ but r^2 is upheld, our deductions would have to be altered and we would neither get (4) nor its equivalent (6), that is, Milne's scale of τ. Vice versa, if our assumption regarding ρ is upheld and if we consequently arrive in $LC + MR$ at Milne's τ-scale, in which $r = \Delta\tau$, then neither r^2 nor $(\Delta\tau)^2$ can be taken as being measured by ρ. Whether this behaviour of ρ in τ can be deduced *a priori* in Milne's theory I do not know. But available *empirical* data seem to speak at least not against our assumption that $(\Delta T)^2$—which is smaller than r^2—is a measure of ρ, for "present evidence points to observed luminosities (ρ) decreasing with distance *not even quite as rapidly* as we should expect. . . ."[3].

"The Relationship between Pithecanthropus and Sinanthropus"

THE article by Dr. G. H. R. von Koenigswald and Prof. F. Weidenreich on the relationship between Pithecanthropus and Sinanthropus in NATURE of December 2 is eminently satisfactory to those anatomists who have not been able to understand why these two hominids should ever have been separated generically. Probably my colleague, Dr. S. Zuckerman, was the first to express doubt on the justification for this distinction, in an essay on Sinanthropus[1], and I have on more than one occasion urged that the Peking hominid is but a Chinese variant of Pithecanthropus[2].

While for some years Prof. Weidenreich, with his first-hand knowledge of the Chinese fossils, has been insisting on their supposed distinctive characters, and has put forward the thesis that they represent an early type of man still more primitive than Pithecanthropus, he now agrees not only that Pithecanthropus and Sinanthropus "are related to each other in the same way as two different races of present mankind", but also that in some significant characteristics Pithecanthropus is the more primitive of the two. If these conclusions are accepted (as they certainly should be) it now becomes necessary finally to discard the generic term Sinanthropus. The Chinese fossils should logically be referred to the species *Pithecanthropus erectus*, or, if it should be thought more desirable as a temporary convenience for purposes of reference, they might be conceded a specific distinction with the name *Pithecanthropus pekinensis*.

The article of Dr. von Koenigswald and Prof. Weidenreich raises again the whole question of the validity of the morphological evidence upon which physical anthropologists often seem to depend for their taxonomic conclusions. For example, the authors use the remarkable argument that, because the femora ascribed to Pithecanthropus of Java show a marked degree of platymeria such as is not found in the femora of 'Sinanthropus', therefore they probably do not belong to Pithecanthropus. This statement would provide a pretty exercise in logical analysis. A similar process of reasoning would also lead to the conclusion that, because a femur excavated from a Neolithic barrow shows more platymeria than the femur of a modern Englishman, therefore it cannot belong to *Homo sapiens*! In any event, an acquaintance with recent literature might have informed the authors of a short, but not unimportant, paper by the late Dr. Dudley Buxton on platymeria and platycnemia[3] in which evidence is adduced in support of the thesis that these characters may have a nutritional basis, and no racial significance.

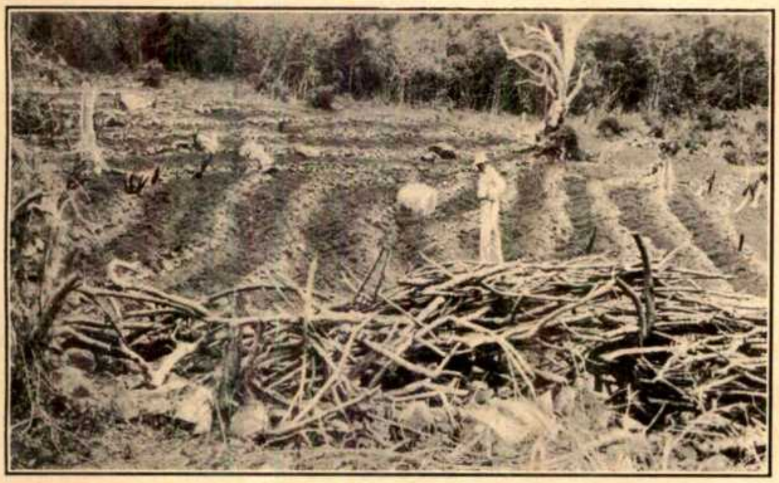
Influence of the Geology of the Virgin Islands on Local Agricultural Practices

WITH the exception of Anegada, Santa Cruz, and part of Virgin Gorda, the Virgin Islands are hilly and rugged. There is in most cases a long narrow backbone rising to about 1,000 ft. with numerous lateral spurs sloping steeply to the sea. Owing to centuries of cultivation and charcoal burning, there is no virgin forest. The predominant vegetation is dense secondary bush in various stages of seral development. Many of the hills are stark naked, while others exhibit a sparse retrogressive xerophytic vegetation.

According to Earle[1] and Hardy[2], the islands are largely composed of enormously thick dynametamorphosed sedimentary tuffs lifted up from the ocean bed by volcanic forces. To quote Earle: "The effect of these dynamic forces has been to lift the sedimentary beds bodily on end into a highly inclined position without obliterating the original stratification. These stratified metamorphic beds which cover by far the greater part of the presidency invariably strike East and West, which fact is doubtless responsible for the alignment of the islands in that general direction. They always dip very steeply, varying from 45° to 90° South and averaging 70°."



The tops of these highly inclined beds have frayed off and are scattered down the slopes in the form of flags of various sizes mixed with soil derived from them. This soil ranges from gravel to loam. The surface is thickly covered with denuded and weathered fragments. Such land at first sight appears extremely inhospitable. Yet owing to the scarcity of flat land, most of the cultivation is done on these talus slopes, which offer certain unique advantages.

After felling the secondary forest, the first step in the preparation of the land is the separation of flags from the soil. The disposal of the flags presents a problem which is easiest solved by placing them in rows along the contours. This is a common practice among the peasants. A few more alert individuals have made better use of the peculiar advantages to hand and have gone in for stone terracing out and out. Needless to say, all manner of terracing is seen, from the primitive arranging of stones in rows to admirable terraces.

To conclude, it will be seen that much of the land in the Virgin Islands can be stone terraced by the peasant himself at no cost apart from his labour. So far as I am aware, no inducement is offered to peasants in the British Virgin Islands to undertake such permanent improvement of their land.

Dioximaleic Acid Oxidase Action of Peroxidases

Banga and Szent-Györgyi[1] recently described a new enzyme, dioximaleic acid oxidase, which catalyses the aerobic oxidation of dioximaleic acid to the corresponding diketo acid.

It was shown in a previous paper[2] that hydrogen peroxide must play an important part in the mechanism of the ferment, because catalase inhibits the reaction between oxygen, ferment and dioximaleic acid completely.

We have undertaken preparations and purifications of the dioximaleic acid oxidases from different plant sources, such as *Rumex acetosa*, *Fraxinus excelsior*, *Prunus Padus*, *Syringa vulgaris* (leaves); horse-radish roots and cauliflower. Many different purification methods were used, as fractional precipitations with salts and organic solvents, absorptions, electrophoretic experiments and others. The removal of impurities by precipitation with lead acetate was especially successful in many cases. Thus the activity of the cauliflower juice was increased in one operation eight thousand times. Very high degrees of activity were obtained, that is, 40,000 c.mm. of oxygen per minute per mgm. of ferment from horse-radish. The starting materials showed activities of 1 to 10. All of the purified preparations showed the typical peroxidase spectrum, 645, 550 and 500 mμ[3].

The ratio dioximaleic acid oxidase/purpurogallin number always remained practically constant in spite of all our attempts to separate the two activities from one another. Moreover, this ratio was nearly constant, whatever the source of the ferments. The purpurogallin number of the most active preparation from horse-radish was 900. The hæmatin content agreed with the figures of Elliott and Keilin[4]. Heavy metals other than iron were practically absent.

Determinations of the inhibitory effect of various reagents revealed remarkable differences between the dioximaleic acid and the purpurogallin tests. Hydrocyanic acid inhibits completely in the latter, incompletely and irregularly in the former. We think this irregularity, noticed first by Banga and Szent-Györgyi, must be connected with a strongly stimulating effect of hydrocyanic acid on the autoxidation of the dioximaleic acid with the subsequent formation of hydrogen of peroxides, which we have observed. Fluoride and azide inhibit in both tests though not to equal degrees, copper salts only in the dioximaleic acid test. Carbon monoxide inhibits only in the dioximaleic acid test. This inhibition is sensitive to light.

Heating ferment solutions to different temperatures caused qualitatively parallel inactivation in both tests.

The results mentioned indicated that the dioximaleic acid oxidase was a hæmin protein. Experiments with pure cytochrome *c* confirmed this conclusion[5]. We found previously[2] that cytochrome $c + 2\gamma$ of $Mn^{\cdot\cdot}$ were able to catalyse the oxidation of the dioximaleic acid.

We now find that manganese produces hydrogen peroxide by stimulating the autoxidation of the substrate. ($Fe^{\cdot\cdot}$-ions, but not $Cu^{\cdot\cdot}$, $Cr^{\cdot\cdot\cdot}$, $Ni^{\cdot\cdot}$ and $Co^{\cdot\cdot}$, stimulate the autoxidation, but practically no hydrogen peroxide remains in the solution, as it is removed by a secondary, peroxidatic reaction between $Fe^{\cdot\cdot\cdot}$, hydrogen peroxide and dioximaleic acid.) Thus the manganese can be entirely replaced by the addition of a small amount of hydrogen peroxide. The hydrogen peroxide, which does not disappear during the reaction, seems to take part as well in the reduction of the $Fe^{\cdot\cdot\cdot}$ as in the oxidation of the $Fe^{\cdot\cdot}$. Analogous mechanisms have been proposed for the catalase[6]. The cytochrome remains mainly reduced until all of the substrate is oxidized. Then the cytochrome is immediately oxidized and partly destroyed by the hydrogen peroxide. Manganese or hydrogen peroxide can be replaced by hydrocyanic acid, which stimulates the hydrogen peroxide production and does not inhibit the reaction because cytochrome *c* gives no compounds with hydrocyanic acid at this *p*H. We have here interesting examples of hydrogen peroxide maintaining, or hydrocyanic acid stimulating, a hæmin protein catalysis.

On the basis of the experiments described above, the possibility was considered that the natural dioximaleic and oxidase could be identical with the peroxidase. However, its manner of reaction in the dioximaleic acid and in the purpurogallin test might be different. In the latter the peroxidase is supposed to remain all the time in its ferric state[3]. In the former, on the contrary, we were able to demonstrate the reduction of the ferric to the ferrous state. If solutions of peroxidase preparations plus dioximaleic acid are shaken with air the colour turns from brown to red with absorption bands appearing at 580 and 545 mμ, belonging to the $Fe^{\cdot\cdot\cdot}$-hydrogen peroxide-peroxidase II[3] or to a hypothetical $Fe^{\cdot\cdot}$-oxygen-peroxidase, or to a mixture of both. If the air is rapidly replaced by carbon monoxide the bands of the $Fe^{\cdot\cdot}$-carbon monoxide-peroxidase (578,543) appear. Thus a valency change, ferric $\rightleftarrows$ ferrous, is involved in the reaction of the ferment with dioximaleic acid, but not with hydrogen peroxide plus pyrogallol.

The differences found in the experiments with inhibitory substances thus may be explained, and there is no sufficient reason for the assumption that the dioximaleic acid oxidase and the peroxidase are different ferments. Our results give an example of a ferment, acting in a different manner with different substrates. They also show that the characterization of ferments exclusively on the basis of the effect of inhibitory reagents may lead to mistakes. Differences may be due to the substrates and not to the ferments themselves. Finally, the dioximaleic acid is remarkable because it allows the peroxidase to produce the necessary hydrogen peroxide spontaneously. A detailed report will be published elsewhere.

Diurnal Rhythms in the Axolotl Larva and in Drosophila

DURING spring and summer of this year, I made some experiments with the intention of throwing light on the physiological mechanism of diurnal activity rhythms. An account of some of the main results follows. It is hoped to publish full details of the experiments at a later date.

The motor activity of axolotl larvæ was recorded by means of a simple actograph. The animals were kept in a shallow layer of water. Their activity caused movements of the water surface, which were recorded on a slowly moving smoked drum, by means of a float connected with a light lever.

The larvæ showed a pronounced diurnal rhythm, under normal conditions of alternating daylight and darkness, being more active at night. If the larvæ were put in continual darkness, the rhythm persisted. If, however, they were subjected to alternating illumination and darkness, so controlled that the illumination phase was made later and later by gradual stages, the rhythm could be reversed. The animals were then active during the real day (this was by now the dark phase) and quiet at night (the artifically lighted phase). Evidently, the rhythm is primarily determined by light; but there is also an inherent rhythm revealed by the persistence of activity cycles in continual darkness.

I was unable to detect any diurnal activity rhythm in metamorphosed individuals.

Hypophysectomized larvæ are active by night and quiet by day, like normal ones; but only so long as the normal illumination cycle acts upon them. In continual darkness, the distribution in time of their activity at once becomes quite irregular. Thyroidectomy does not interfere with the activity rhythm. It appears then that the hypophysis plays an important part in the inherent rhythm revealed by normal animals kept in darkness.

The interrelations of internal and external factors in determining diurnal rhythms were also studied in Drosophila. Here a 'hatching rhythm' appears. Under normal lighting conditions, most of the adult flies emerge from the pupa in the hours just before sunrise. The interval between consecutive 'emergence peaks' is always twenty-four hours, whatever the temperature, and it appears that light is the primary controlling factor. If the culture is transferred to continual darkness, the rhythm continues unmodified at medium temperatures. At low temperatures the intervals are slightly lengthened, at high temperatures shortened.

By altering the temperature, the intervals between emergence peaks were varied between 2½ days and 16 hours. The 'inherent rhythm' revealed by the persistence of emergence maxima in darkness is therefore sensitive to temperature. It appears to have a temperature coefficient obeying van't Hoff's rule.

If a culture is kept from the first in continual darkness, no hatching rhythm appears. The rate of emergence is affected by temperature; less flies than usual emerge during and just after a rise, and more during and after a fall. However, temperature change does not induce a persisting rhythm. Light, on the other hand, can induce such a rhythm. One single illumination period, provided that it lasts for at least 4 hours, induces a 24-hours rhythm in a culture kept beforehand and afterwards in continual darkness. The temperature relations of the rhythm thus induced are as follows: (1) whatever the temperature at the time of illumination, the rhythm has a period of 24 hours, provided that the temperature does not afterwards change; (2) subsequent change has the usual effect (lower temperature slows, while higher temperature hastens, the rhythm). The fact that a 24-hour rhythm can be induced by a single illumination period, independently of temperature, is remarkable and the nature of the factors ensuring that the induced rhythm shall have a period of 24 hours remains, for the present, obscure.

The experiments were carried out in the Department of Zoology, University College, London. I wish to thank Prof. D. M. S. Watson for kindly allowing me to work in his Department, Mr. C. P. Wells for much helpfulness, and Mr. N. H. Howes for allowing me to use his intact and operated axolotls.

HANS KALMUS.

Points from Foregoing Letters

REGENERATED cellulose sheet is shown by D. G. Drummond to be birefringent in a way which might reasonably be expected from extrapolation of Spence's results for sheets made from cellulose esters. The relative unimportance of side-chain orientation in cellulose itself results in a generally greater birefringence and a change in the 'slow ray direction' as compared with the ester films. Numerical results for regenerated cellulose sheets are given.

A. Schallamach finds that the heat conductivity of commercial rubber at the temperature of liquid air is about one fortieth of that at room temperature.

S. E. Williams has examined the absorption of the hydrogen line at 1215·7 A. in nitrogen, water vapour, oxygen and air. Nitrogen is transparent and water vapour absorbs very strongly. Oxygen and air absorb much more strongly than has previously been believed. No absorption appears to occur until the partial pressure of oxygen is about 0·04 mm., and the absorption coefficient varies in the lower part of the absorption range. If the emission of 1215·7 is responsible for short-wave fadeouts, the radiation will penetrate to about 80 km. before it is absorbed in producing ionization.

Making the assumption that the field responsible for the interaction between elementary nuclear particles is a two-particle field, so that a mesotron is always emitted or absorbed in conjunction with a neutrino or antineutrino, P. L. Kapur states that it is possible to derive the forces between the particles and to explain the phenomenon of β-disintegration.

That the three theories (1) the universe expands, (2) c decreases, (3) atomic frequencies speed up, are all equivalent and must not be looked upon as alternative explanations is stressed by K. R. Popper. The systems of measurements underlying these theories are compared and an observational approach to Milne's 'dynamical' time is mentioned. It is asked whether in (2) and (3), luminosities do not decrease with time (measured in frequencies) instead of distance.

Now that it is admitted that Sinanthropus is but a variant of the Pithecanthropus type, W. E. Le Gros Clark suggests that the generic term Sinanthropus should be discarded. The Peking fossils should be referred to the species *Pithecanthropus erectus*, or at the most they might be conceded a specific distinction with the name *Pithecanthropus pekinensis*. The argument that the femora ascribed to Pithecanthropus of Java do not really belong to this genus has no logical basis.

F. A. Squire states that, owing to geological peculiarities, the soils of the Virgin Islands are composed largely of flags. This makes stone terracing a practical, inexpensive proposition.

B. Swedin and H. Theorell have extracted and investigated the ferment recently described as new and called dioximaleic acid oxidase by Banga and Szent-Györgyi. From their observations, Swedin and Theorell conclude that this ferment is a hæmin protein and that it can act in a different manner with different substrates. They finally conclude that there is not sufficient reason for the assumption that the dioximaleic acid oxidase and the peroxidase are different ferments.

H. Kalmus describes experiments on the physiology of diurnal rhythms in axolotl larvæ and Drosophila, dealing with the relation between externally and internally determined rhythms, the action of light, temperature and endocrine factors.

RESEARCH ITEMS

Australian Shell Ornaments

A DETAILED study of shell ornaments in use by the aborigines over wide areas in Australia has been made by C. P. Mountford and Alison Harvey, ethnologists of the South Australian Museum (*Records S. Austral. Mus.*, **6**, 2, 1939). These shell ornaments fall into two divisions, one made from the baler shell (*Mela diadema*) and the second from the shell of the pearl oyster (*Meleagrina maxima*) and the smaller pearl shell (*Meleagrina margaritifera*). The pearl shell ornaments are found almost exclusively in western Australia, while with a few exceptions the baler shell ornament is limited to Queensland, Western Central Australia and north-eastern South Australia. The pearl shell ornaments are used for decoration and as objects of ceremonial importance. For the former purpose they are suspended from a belt back and front, while both men and women wear several down the back suspended from a necklace of human hair. In Central Australia the chief aspect of their magical purpose is their potence in charms for women and their healing properties. Various myths are woven round the pearl shell, and a particular chant is sung when the designs, which appear on them, are being engraved. The ornaments are oval in shape and vary from two to eight inches in length. The baler shell ornaments vary in use according to locality; but they may be used as ornaments or for ceremonial purposes. In west-central Queensland, for example, they are used for personal adornment or as a decoration on the haft of a spear-thrower. Among the Dieri, however, the shell ornament had great magical value and was closely connected with the circumcision ceremony, in which it was worn by the initiate as a chest ornament. The Dieri were also the only tribe using the shell for evil magic. In appearance the ornament was an ovate piece of white shell from two and a half inches to five inches long. Designs were engraved on the concave face and red ochre rubbed in. These shell ornaments were intended for male use only, but in certain circumstances, more or less ceremonial, women were allowed to handle or use them.

Scaphocephaly among Australian Aborigines

IN an examination of 2,000 skulls of Australian aborigines, Frank J. Fenner, honorary craniologist of the South Australian Museum, has found five cases of scaphocephaly (*Records S. Austral. Mus.*, **6**, 2; 1939). Two forms of scaphocephaly are recognized, of which one is descriptive of the form of skull characteristic of the Eskimo, and found among the Australian aborigines, and the second is pathological —a premature, probably fœtal, synostosis of the sagittal suture present in a very long narrow type of skull; this is a rare condition occurring in many races, European, Egyptian, Negroes, etc. The specimens here described belong to the second class. Premature closure may, of course, occur without any trace of scaphocephaly. Of the skulls examined three were adult (male) and two juvenile, 4–5 years and 6 years. Detailed observations and comparisons with such normal material as was available were made. In the result these observations would go to support the conclusion of Hamy that scaphocephaly is the result of the synostosis of the two parietal bones, that this synostosis is the result of a pathological process, probably inflammatory, and that the deformation occurs only when the fusion begins during intrauterine life at a time close to the commencement of the ossification of the cranial vault. In two of the skulls and in one described in 1867, fine vascular pores covering the surface of the bone gave evidence of a pathological condition. Three of the skulls examined showed a synostosis of the squamous suture, but of 1,200 normal aboriginal skulls, three only showed fusion of the squamous suture—all aged individuals. Probably this condition is here related to the sagittal synostosis and an outcome of the same underlying pathological cause.

Doubling the Chromosomes of Nicotiana

H. E. Warmke and A. F. Blakeslee (*J. Hered.*, **30**, 419–432; 1939) have successfully induced the doubling of chromosome numbers in *N. Sanderæ*, *N. Tabaccum* × *glutinosa*, and *N. glutinosa* × *N. sylvestris*, by treating with colchicine. Treatment of seed gave as high as 100 per cent tetraploids of *N. Sanderæ*. A new method of application by using an emulsion spray, consisting of stearic acid, morpholine and lanolin, has been found more efficacious than the water spray. It is noteworthy that mixtures of fertile and sterile flowers on one plant were not obtained from seed treatment, but the whole plant was either diploid or tetraploid in behaviour. On the other hand, stomatal size in these plants was not always correlated with fertility. This indicates that some of the plants may have been periclinal chimæras.

The Chrysanthemum Midge

A MINUTE, red, two-winged fly which produces small conical galls upon the leaves and stems of chrysanthemums has been recognized as a serious pest in the United States, and has appeared twice in Great Britain during the last decade. The present attack is, fortunately, somewhat limited, but Dr. H. F. Barnes has published a timely description of his studies of the insect (*J. Roy. Hort. Soc.*, **64**, Pt. 2; Nov. 1939). The midge, which has usually been recorded as *Diarthronomyia hypogœa*, infests commercial late-flowering chrysanthemums, but will not apparently spread to the earlier summer kinds, nor to common, closely related weeds. Five generations appear every year in cool greenhouses, but in heated structures there are eight. The length of time spent in each stage of the life-history appears to depend directly upon temperature, being generally shortened by summer heat. Severely infected plants do not flower. Consistent spraying or fumigation with nicotine provides a complete, though very expensive, control. The most effective prevention, however, is the cutting of infected shoots to ground-level, for the stool cuttings which emerge later from such plants are found to be free from the insects.

Larvæ of British Coleoptera

IN the *Entomologists' Monthly Magazine* of November and December, Dr. F. van Emden, of the Imperial Institute of Entomology, contributes the first of a series of articles on the larvæ of British Coleoptera (beetles). The object of these contributions is to provide keys to enable the larvæ of the

British members of the order to be recognized as reliably as possible, and the first of these articles deals with the family Cerambycidæ. The material upon which the account is based consists primarily of that available in the collections of the British Museum (Natural History). Important additions, however, were based upon the specimens obtained on loan from the Zoological Museum, Copenhagen. All the thirty-six genera of British Cerambycidæ are included in these keys. Seven of the genera, however, have their characters taken from literature, since no larval material was available. While it will obviously be a lengthy business in dealing with the larvæ of even the chief families of British Coleoptera, the present account is a good beginning, and we hope to see many other groups similarly treated by Dr. van Emden.

Control of the Bean Rust Fungus

A RUST disease of the bean is widely distributed in Lower and Middle Egypt, and its control has formed the subject of a study by Dr. A. F. El-Helaly (*Min. Agric. Egypt, Tech. and Sci. Serv. Bull.* 236, Govt. Press, Bulâq, Cairo, P.T. 4, 1939). Spraying with Bordeaux mixture of half per cent strength was found most effective, and yielded the significant net profit of from one to four Egyptian pounds per feddan. Chocolate spot, caused by *Botrytis fabæ*, was also controlled by the same treatment. Sulphur fungicides were tried, but were not found reliable against these particular parasites, and the Bordeaux treatment possessed the further advantage that no physiological check was administered to the foliage.

Vertical Air Currents

SCIENTIFIC Note No. 81 (7) of the India Meteorological Department, by K. P. Ramakrishnan, deals with vertical currents in the first few kilometres over Poona and their possible effect on the measures of upper winds made by pilot balloons assumed to rise at a known constant rate. The vertical currents were deduced from the height-time curves found for balloons by the tail method, which involves measurements of the angle subtended by a tail assumed to hang vertically beneath the balloon, with the aid of a special graticule in the pilot balloon theodolite. The method is probably accurate enough for the purpose of revealing vertical currents of the strength of those often observed at Poona in the hot season. A more serious source of error in computing the vertical currents arose from the assumption that the differences between the observed rate of ascent (V) and the rates given by the standard formula $V = q\frac{L^{1/2}}{(L+W)^{1/3}}$, where q is a constant for a particular size of balloon, L is free lift and W is weight of balloon, are measures of the vertical currents. Actually, the rate of ascent of a balloon is affected by its shape, which is never truly spherical, and, to judge from the performance of the 100-gm. Dewey and Almy balloon, by other factors not yet understood, for with this balloon, so far as observations have been made at the Meteorological Office, the rate of ascent varies roughly as $\frac{L}{(L+W)^{2/3}}$, and not as the square root of that quantity, as is implied by the standard formula. Such sources of error probably do not invalidate two of the conclusions reached by Ramakrishnan; first, that the rate of ascent of a balloon for a given lift and weight is far more variable in the afternoon than in the morning at Poona, and that this is due to the greater magnitude of the vertical currents in the afternoon, and secondly that a method of obtaining upper winds that involves the assumption of a constant rate of ascent of the balloon is thoroughly unreliable in a tropical climate like that of India. The values of vertical velocity found were mostly between 3 km. and 5 km./hour in the afternoon, and occasionally reached 10 km./hour.

Geography of Egypt

A VOLUME entitled "Contributions to the Geography of Egypt", written by J. Ball (Cairo: Government Press. 10*s*. 6*d*.), may be regarded as a comprehensive study of most aspects of the Nile and contains a great deal of new matter as well as facts that are scattered in various publications. Apart from the treatment of the physical aspects of the Nile basin and water, the Faiyum depression is the subject of a lengthy study. Much has already been written on this lake. Dr. Ball points out that the absence of Pliocene deposits proves that the depression cannot have been in existence in those times. The numerous lacustrine deposits of later ages show that a lake of varying height must have existed from early Pleistocene times to the present day, and since there can have been no erosional deepening of the depression while the lowest part was below the surface-level of the lake, its excavation must have been entirely accomplished between the end of the Pliocene and the beginning of the Pleistocene. But the Nile then flowed at much higher levels than to-day, so that its lateral stream could not have effected erosive action at such low levels. Thus, argues Dr. Ball, the Faiyum was hollowed out independently of the action of the Nile: some other agency must have been at work. He concludes that the depression is due to wind erosion in early Pleistocene times, and this theory is supported by what is known of the origin of other depressions in the Libyan plateau such as the oases of Kharga, Dakhla and Qattara.

Drainage of Southern Ireland

THE peculiar trellised pattern of the river system of southern Ireland has attracted considerable attention since Jukes postulated a superimposed origin from an elevated initial surface. Hull modified this hypothesis by invoking fault lines as controlling the right-angled deflections of the rivers. Austin Miller has re-examined the whole problem in a paper entitled "River Development in Southern Ireland" (*Proc. Roy. Irish Acad.*, **45**, Section B, No. 14). One of the most difficult features to explain is the failure of the subsequent at the expense of the consequent rivers in the completion of the pattern which might be expected to have led to the outflow of the Blackwater to Dungarvan Bay and the Lee to Youghal Bay. Conditions appear to favour this completion, for there has been rejuvenation since the present mouths were acquired that would provide the subsequents entering these two bays with the increase in gradient necessary for headward encroachment. Mr. Miller suggests that the explanation lies in the acquisition by the present estuaries of a volume of discharge, by a long process of captures, so much greater than that of their competitors that they have been able to excavate sufficiently rapidly through the hard ridges that attempt to bar their courses and so outrival the strike streams in spite of the softer rock over which the latter flow.

AIR TRANSPORT, INSECTS AND DISEASE

BY DR. A. D. IMMS, F.R.S.

MR. F. G. SAREL WHITFIELD has recently issued a comprehensive article on air transport, insects and disease (*Bull. Entomol. Res.*, 30, 365–442; 1939). The discovery by Shannon in 1930 of the presence of *Anopheles gambiœ*, an insect native to Africa, in the city of Natal, Brazil, and its subsequent spread, directed special attention to the carriage of disease-bearing insects by aeroplanes. Whether *A. gambiœ* was actually transported in a surface vessel or in an aircraft will probably never be known, but, as the result of its entry and subsequent spread, more than 90 per cent of the population around Natal were infected with malaria in 1938. The indexes of malaria-infected mosquitoes are said to be the highest in the history of malaria. The introduction of *A. gambiœ* into South America seems to have had the disquieting results, just referred to, because possibly the native population has very little power of resistance to the African strain of the disease carried by the mosquito.

The situation as regards yellow fever is potentially far more serious than that concerning malaria. Shannon, Whitman and Franca in 1938 made a significant contribution to what is known of the vectors of yellow fever. They produced positive evidence of the mosquitoes *Aëdes leucocelœnus* and *Hœmogogus capricorni* being concerned in the transmission of jungle yellow fever in Brazil. Until this discovery, evidence of any mosquito other than *Aëdes œgypti* being implicated in the transmission of yellow fever was furnished solely on the results of laboratory experimentation. The aspect of most importance with regard to aerial transport, arising out of recent research on yellow fever epidemiology, seems to be the discovery of vast areas in Africa and South America where the disease prevails in epidemic or endemic form. It is obviously of prime importance that aircraft operating within and from Africa and South America should be maintained free from all insects. Mr. Whitfield points out that the proposed reserve Empire war route across Africa to India and Australia will present an urgent problem in this connexion, and that it would be unwise to inaugurate such a service until the proper control of insects in aircraft has been achieved. In view also of the proved existence of considerable insect populations in the upper air, the question of the possibility of aircraft collecting insects while in flight arises. The ability of insects to survive air transit is another problem. *Aëdes œgypti*, for example, has been proved to be able to endure a journey of at least 9,580 miles in length and of 6½ days duration.

Diptera are overwhelmingly the commonest insects found in aircraft. Species of Musca are very frequent and also many kinds of mosquitoes. The control of insects in aircraft is a difficult subject. As Mr. Whitfield remarks, it involves the co-operation of the entomologist, the chemist and the engineer, an airline operating company and a commercial aircraft manufacturer. Such joint approach to the problem, he holds, is essential if progress is to be made. No adequate and reliable method of control of insects in aircraft has yet been devised: the problem of controlling insect invaders of aerodromes needs also the fullest attention. Little will be gained, the author adds, from further research upon insects found in aircraft—the real problem being the effective means for their destruction.

THE ROTHAMSTED EXPERIMENTAL STATION

BY E. J. ROBERTS

THE annual reports of the Rothamsted Experimental Station are of more than ordinary interest to farmers and research workers. The amount and variety of the fundamental investigations carried out in the laboratories, linked with the field work not only at the Rothamsted and Woburn farms, but also at a number of commercial farms scattered over England, give these reports a character and importance of their own. The improvements in the technique of field experimentation, evolved at the statistical department, have not only given more accuracy to the usual trials, but also have widened the scope of investigations by making it possible to detect small differences, and to measure, for example, the interaction effects of certain manures.

In the report for 1938*, published recently, an account is given of the experiments on wheat, including those on the continuous growing of this crop, and those on the value of leys, green manures, and fallows for preceding the wheat crop. The experiment on the continuous growing of wheat has now been in progress for nearly a hundred years, and it is interesting to note that the land has not become what might be termed 'wheat-sick'; the main difficulty has been in the suppression of weeds rather than in the actual growth of wheat. This conclusion is important at the present time. Why, it is asked, when these experiments prove clearly that wheat can be grown continuously on the same land, should difficulties arise when the crop is grown for a few years in succession on certain mechanized farms? An explanation is offered to the effect that the nature of the soil is responsible. Wheat is a heavy-land crop, and, on the heavy Broadbalk soil, the crop remains healthy; diseases and pests are present; but they do little damage. The lighter soils, however, especially the light chalky soils on which many mechanized farms are situated, are more liable to contain diseases, such as take-all, lodging diseases and others, and the crop suffers more heavily.

---

* Rothamsted Experimental Station, Harpenden. Report for 1938. (Harpenden: Lawes Agricultural Trust.) 5*s*.

The effects of temporary leys, green manures, and fallows as preparation for wheat are also under investigation, and the field trials are combined with work in the chemistry department to follow seasonal changes in nitrates, ammonia, and readily decomposed crop residues in the soil; an attempt is made to trace the form in which available nitrogen is carried over from one year to another.

Sugar beet is the subject of extensive investigations carried out on a variety of soils, in conjunction with the sugar factories; the extent of these experiments may be judged from the fact that, in 1938, there were 38 experiments, with 1,360 plots. These experiments are mainly concerned with manurial responses in the various soil groups. The year 1938 was disappointing as regards this crop, the yield, expressed in terms of sugar, having been 12·5 cwt. per acre less than the average of the previous four years.

Other long-term experiments recorded are those on organic manuring by means of green crops, town refuse and straw. The question of organic manuring, and of the use of town refuse in particular, is of more than ordinary interest to-day. It is interesting to note that a prepared town refuse gave encouraging results in a comparison with sulphate of ammonia, dung and rape dust. The refuse gave rather higher yields than farmyard manure providing equal nitrogen in three out of four comparisons, and did almost as well as sulphate of ammonia providing half as much nitrogen.

Other sections of the report also contain much of interest, for example, those on the farm, and the report on fungus diseases at Rothamsted and at Woburn. Details are given of the experiments at outside centres. It is interesting to observe that in such experiments, which are designed at the Station, the degree of precision compares favourably with that in the experiments carried out at Rothamsted and Woburn.

ELECTRICITY SUPPLY IN AUSTRALIA AND NEW ZEALAND

THE rapid expansion in the practical applications of electricity in parts of Australia and New Zealand and the new problems to which it gives rise is well illustrated in the *Electrical Times* of November 23. In England we consider a 'County Council' as a body which has definite connexions with general public services as, for example, health, education, highways and the like. This is not the case at Sydney, New South Wales, where the 'Sydney County Council' was created in 1935, by a special Gas and Electricity Act, which enables it to assume ownership and control of the electricity department which up to that time had been in the hands of the City Municipal Council. This County Council has only five members, two of them elected by the City Municipal Council and the remaining three being shared by the municipal councils of thirty-two other townships. For election as a councillor, the candidate must be qualified by being eligible for aldermanship in one of these constituencies. This arrangement has points of similarity with that of our own Joint Electricity Authorities (J.E.A.). The Sydney County Council supplies electricity directly to the public in the city, thirty-two suburbs and for street lighting in the city. In addition it gives a bulk supply to fourteen other municipal authorities who do their own distribution, and to a company which distributes to two other municipal areas. The area throughout which a direct supply is given is about 150 sq. miles and its population is about 900,000. The 'bulk' areas are about 750 square miles and have about 150,000 inhabitants. Altogether the County Council supplies electricity over an area of approximately 900 sq. miles and having more than a million inhabitants.

The County Council co-operates with the railway department, which has a supply station of its own so as to level the output and so cheapen the cost. The interchange of energy between them is adjusted so as to be nearly equal at the end of each quarter. The main business of the County Council's Electricity Sales Branch is three-fold: first, to develop and advertise the use of electricity in commerce, industry and the home, secondly to sell electrical apparatus and thirdly to deal with contracts for large supplies of energy. The sale of apparatus, ranges, water-heating systems and wash-boilers is arranged for cash or on hire purchase. Instantaneous heaters are sold for cash only. The installation work is also sold by the Council. Two forms of merchandizing are employed. In one the Council buys the equipment and sells it to the consumer. In the other the Council sells the apparatus for the supplier on a commission basis. The basis of the Council's service policy is "make friends with the consumers. This is effected by the advisory service, which not only develops the use of electricity but keeps the consumers satisfied".

Reports from the New Zealand municipalities, which largely utilize hydro-electric power, show that there is considerable anxiety in both North and South Islands as to how to meet the coming winter loads. Deputations have approached the Government and pointed out the limitations of the hydro-electric power available and the urgent need of steam-driven plant to cope with the expected peak load of 1941. The general manager of Christchurch Electricity Department ends his report with these words: "The city of Christchurch is now so completely dependent upon electricity supply in its public services, which include sewerage and water pumping, that the electricity supply intimately concerns hygiene and health as well as the general public life". It looks as if in a few years' time these words would apply to many cities spread over the whole world.

The electrical engineer of Dunedin says that they cannot always count on getting the same ample supply of water-power every year. In severe frosts in winter time very little water-power may be available. The great demand for instantaneous water heaters for baths shifts the maximum load from the afternoon to the early morning. This makes it difficult to devise an equitable multi-tariff meter system which will charge the consumer most at times when the load is a maximum at the supply station.

PALÆOLITHIC MAN IN THE NORTH MIDLANDS

NOW that the text of Mr. A. Leslie Armstrong's Wilde Memorial Lecture is available in full (*Mem. and Proc. Manchester Lit. and Phil. Soc.* 1938–39, 83, 1939. Separate, pp. 30, with plates. Price 1*s*.), the results of the investigations summarized in that lecture call for more extended notice than was possible at the time of its delivery on March 14 last (see NATURE, **143**, 512 ; 1939). As Mr. Armstrong pointed out, the North Midland area, that is, the Trent basin north of Leicester, has yielded evidence which now makes it possible to demonstrate on a stratigraphic showing the presence of man here during every stage of the palæolithic period more completely than for any other part of England.

An important consideration, which Mr. Armstrong emphasized in the opening of his lecture, was the constant oscillation in climatic and environmental conditions during the Ice Age, while at the same time he dwelt on the distinction worked out in detail by the Abbé Breuil between the core culture peoples associated with inter-glacial periods and the flake culture races associated with glacial periods. The changing environment not only brought about racial movement, but also necessitated cultural development and the elaboration of new types of implements, although with the setting in of less favourable conditions once more old and traditional types at times were revived.

Mr. Armstrong's evidence was drawn in part from recent explorations of the Trent Valley gravels, still in progress, in part from his now well-known investigations in Yorkshire and Derbyshire caves and on certain sites in Lincolnshire.

LOWER PALÆOLITHIC AGE

The first record of Lower Palæolithic implements in the Trent Valley was made in 1928 in a gravel pit at Burton. Further investigation by Mr. Armstrong and others has now shown that all the recognized forms of both the core and the flake industries from Pre-Chellean to Mousterian occur here. These finds come from three horizons of gravel, comprising two old river-terraces and a high-level glacial gravel. The main interest of the investigation, therefore, lies not merely in the occurrence of this range of types here, but also in the correlations which it has made it possible to attempt.

Recent investigation has also determined that the gravels, though they have been described as "Old Valley Gravels", are actually of sub-glacial origin. The low terrace comprises the infilling of an ancient valley of which the floor lies far beneath the bed of the Trent and through which that river has cut its channel. The most important deposits of the series are the high-level gravels, which mantle extensive areas on both sides of the valley. In the deposits three zones are distinguished, of which A, the oldest, in certain of the Hilton sections, rests upon bed-rock, the Keuper marl, while in others it thins out until B rests on that rock. In other sections B and C zones, separated by a band of sand in gravel particles, alone are present.

As regards archæological content, artefacts found in Zone A *in situ* fall into two well-defined groups, of which the first, consisting of pre-Chellean, Chellean and a Levallois flake are patinated a deep chocolate-brown, heavily rolled and evidently derived from an earlier deposit ; while the second is patinated bluish-white and appears to be contemporary with the gravel. In the latter group were a typical Acheulean hand-axe, as well as a late Clactonian (or Tayacian) flake and two slightly rolled Levalloisian flake tools. The contents of Zone B, though less numerous, are the same as in A, but differ materially in condition. All are heavily rolled, but some Levallois and Clacton types are only slightly abraded. The patination suggests that the abraded artefacts are derived from Zone A.

Zone C exhibits extreme contortion, suggesting lateral pressure, or collapse under the influence of melting snow and ice. It has not yielded any Acheulean types, but two heavily rolled Clactonian and a Levalloisian flake, both only slightly abraded and, therefore, possibly contemporary with the gravels, have been found. The latter are important for correlation purposes.

For these conditions certain tentative interpretations are put forward by Mr. Armstrong. In the first place, he suggests that the co-existence here of core and flake may be due to the fact that they are not, as concluded by the Abbé Breuil, two distinctive cultures, but two techniques ; and in that event, while the flake industry was indeed almost exclusively employed by the ancestral Mousterian race, Acheulean and later peoples may have employed Clactonian and Levalloisian techniques where necessary or expedient. Secondly, that Zone A represents a deposit laid down at the end of the great Acheulean inter-glacial—possibly a remnant of the Little Eastern glaciation equated with Würm—which has been ploughed away and incorporated in Zone B. Thirdly, that Zones A and B respectively correspond with the two glacial phases separated by an interglacial phase, associated with a Mousterian (Late Clactonian or Tayacian or Micocquean in its earlier phase) observed in the Pin Hole section, Cresswell Crags. Fourthly, Zone C may be either a melt-out of Zone B, or a local re-advance of the ice after the B stage, or the final glaciation (Hessle) of the northern region.

MIDDLE PALÆOLITHIC AGE

In dealing with the Middle Palæolithic Age, Mr. Armstrong's evidence is chosen entirely from the cave explorations on which he has been engaged with the assistance of a Research Committee of the British Association for more than thirteen years. The Pin Hole Cave, Cresswell, has given a type cave section for Britain with occupation ranging from Mousterian I to the developed Aurignacian of the Upper Palæolithic which is preserved as an 'ancient monument'. The deposits consist of two beds of cave earth, of which the lower and earlier extends from Early Mousterian to the proto-Solutrean which with Aurignacian appears in the base of the upper bed.

As already mentioned, the lower deposit affords evidence of two glacial phases with a warm inter-glacial. If indeed these levels are correctly correlated with the Little Eastern glaciation and thus with Würm, this interglacial affords evidence of a North Midland retreat of the ice in relation to the Little Eastern which has not previously been recorded.

UPPER PALÆOLITHIC AGE

The highly significant evidence for the Upper Palæolithic period, drawn in part from cave deposits, in part from north Lincolnshire open sites, must here be dismissed in brief. Among the more interesting conclusions to which excavation has led, is the confirmation of the absence of any gap in continuity between Upper Palæolithic and Mesolithic, and at the close of the Aurignacian period the remarkable local variability in type of the elements of the culture. Two finds which must not be passed over are a fragment of mother-of-pearl skilfully shaped, possibly part of an amulet, and a cowrie shell. *Cyprea moneta*, from the Pin Hole Cave.

HEARING TESTS

IN the December number of the *Bell Laboratories Record,* Mr. H. C. Montgomery, of the Acoustical Research Department of the Bell Laboratories, discusses results obtained by subjecting many of the visitors at the World's Fairs to tests of the quality of their hearing. The records obtained enabled him to get nearly three-quarters of a million of records carried out in the same way.

The Bell system deals in hearing, and to get the best service it is important that it have available trustworthy data on the hearing characteristics of the American people. The tests are given in soundproof rooms arranged to seat seven visitors, each partially screened from the others. Both the tests and the instructions are given through telephone receivers; the visitor holds the receiver to his ear with one hand whilst he marks the results on a card with the other. Two types of tests are given, with separate booths for each. In one the visitor hears spoken words, which are two numbers, such as "eight-six". The numbers heard are written on the card, and each successive pair is at a lower volume. Twelve pairs of numerals are spoken at successively lower volumes; and then the test is repeated with a different series. In the other type of test, the two numbers are replaced by pure musical tones, each tone being sounded from one to three times, and the listeners write down the number of times they hear the tone. Five tests, each consisting of nine sets of tones at successively lower volumes, are given. The first is a moderately low pitch, 440 cycles per second, which corresponds to *A* above middle *C* on the piano. Each following test is one octave higher in pitch and thus the hearing is tested at 440, 880, 1,760, 3,520 and 7,040 cycles.

At the San Francisco Exposition were three booths, one arranged for word tests, one for tone tests, and one that could be used for either. At New York eight booths were provided for each type of test. Only the tone tests were recorded. The word tests give only a check on one's ability to understand spoken words, while the tone test, by providing data at five frequencies over the most important part of the aural range, is more suitable for study and analysis. Before a record is made on the test card the attendant puts a mark on it to indicate whether the visitor is male or female, coloured or white, and to which of the five age groups the person belongs, the age groups extending in five groups between 10 and 60. The cards are then run through a Recordak machine which analyses the curves marked on them. The cards are then run through tabulating machines which analyse and sum up the data. The results of this survey indicate a definite falling in hearing acuity with age. This is in harmony with previous data, which indicate a definite falling off in hearing acuity with age, particularly noticeable at the higher frequencies. A rather remarkable fact is that at the low frequencies the falling off with age is less for men than for women, while at the higher frequencies it is less for women than for men. In the lowest age group the difference between men and women is small, but even here the advantage is slightly with the men at low frequencies and with the women at high frequencies. In the age group 50–59 years the difference becomes much more pronounced.

The curves show that for young ears and low frequencies, the tests are grouped fairly closely around the average. For older persons or higher frequencies, the distribution spreads and the number with average hearing becomes small; most differ from the average in both directions and in varying degrees. The interpretation of the losses at various frequencies needs a specialist, since the evaluation of the effect on one's ability to hear in any particular band of frequencies is a function of many factors. It has been found that one's ability to understand speech can be determined from the average of his hearing losses at 440, 880 and 1,760 cycles per second as compared with good young ears. If this average is 25 db. (decibels), there may be some difficulty in hearing in auditoriums and churches, while if it is 45 db. there may be difficulty in hearing in direct conversation. Only if the hearing loss is as much as 65 db. will there ordinarily be much difficulty in hearing over the telephone.

By use of these figures, the tests indicate that about one out of twenty-five persons have difficulty in hearing in auditoriums; one in 125 will have some difficulty in direct conversation; and one in 400 over the telephone. Two out of five men between 50 and 59 will have a loss of at least 25 db. at 3,520 cycles, while only one in five women will have as great a loss at this frequency. It was found also that about one in 25 of the group from 10 to 19 had a loss of at least 25 db. at 7,040 cycles. This figure is important, because it has been found that young people with a hearing loss of this amount will often be found to become progressively worse in later years, but if remedial measures are taken immediately, impairment may be largely checked. No significant difference was found between the visitors to the Fairs who were resident in New York and those resident in San Francisco. The time of day at which each test was taken was marked on the card and permits a comparison of the results for different periods of the day. No consistent difference was found between early morning and late afternoon. There is thus no indication of any effect being produced in the hearing by fatigue.

SEVENTY YEARS AGO

NATURE, vol. 1, January 13, 1870

Government Aid to Science

ALFRED RUSSEL WALLACE, in a letter to the Editor, writes: "The public mind seems now to be going mad on the subject of education; the Government is obliged to give way to the clamour, and men of science seem inclined to seize the opportunity to get, if possible, some share of the public money. . . .

"Now, sir, I protest most earnestly against the application of public money to any of the above specified purposes, as radically vicious in principle, and as being in the present state of society a positive wrong. . . . I uphold national education, but I object absolutely to all sectional or class education; . . . The broad principle I go upon is this,—that the State has no moral right to apply funds raised by the taxation of all its members to any purpose which is not directly available for the benefit of all. . . . If we follow this principle, national education is not forbidden, whether given in schools supported by the State, or in museums, or galleries, or gardens, fairly distributed over the whole kingdom, and so regulated as to be equally available for the instruction and amusement of all classes of the community. But here a line must be drawn. The schools, the museums, the galleries, the gardens, must all alike be *popular* (that is, adapted for and capable of being fully used and enjoyed by the people at large), and must be developed by means of public money to such an extent only as is needful for the highest attainable *popular* instruction and benefit. All beyond this should be left to private munificence, to societies, or to the classes benefited, to supply."

A New Thames Subway

THE importance of geological data on the extent of the London Clay was emphasized in an article by J. Prestwich, F.R.S., on the second Thames subway. "The first to apply this knowledge was Mr. P. H. Barlow, C.E., F.R.S., who fixed upon a spot intermediate between London Bridge and Limehouse (where the thickness of London Clay must be about 80 ft.), and at a sufficient distance below London Bridge to render an underground passage of the Thames a work of great public utility. . . . The tunnel is 7 feet in diameter, and is formed by cast-iron tubing in lengths of 1½ feet each, each ring being composed of thin segments with a key piece. An iron shield, devised by Mr. Barlow, was pushed on in advance of the work. . . . The passage under the river will be made in an omnibus, by means, probably, of a stationary engine; and lifts on either side will take the passengers up and down [the shafts]." The tunnel, 1320 feet long, was begun on April 26, and finished on October 8, 1869, without a single fatal or even serious accident to any of the men employed. It is no longer in use.

On the Periodicities of the Solar Spots

"Messrs. De la Rue, Stewart, and Loewy have for some time past been engaged in investigations [at Kew Observatory], which . . . go to show that there is an intimate and, as yet, unexplained connection between the configuration of the planets and the position and number of the spots on the sun. This result, which at once seems to land us in a sort of modern astrology . . . is . . . questioned by many European astronomers". Accordingly, a digest is given of independent investigations carried out by Dr. Kirkwood and published in the *Proceedings of the American Philosophical Society*. Among his conclusions were that the theory "has been placed beyond reasonable doubt", and the "11-year cycle of spot variation is mainly dependent on the influence of Mercury".

THE oxy-hydrogen light is now largely used in Paris for illuminated advertisements and theatrical purposes. Carts with metal reservoirs containing the compressed oxygen for the supply of customers may be seen in the streets. At the Gaieté Theatre, which is one of the largest consumers, cylinders of magnesia or zirconia take the place of the lime cylinders ordinarily used for this light.

PROF. HELMHOLTZ, of Heidelberg, has been elected a corresponding member of the Physical Section of the Paris Academy of Sciences.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

UNIVERSITY ASSISTANT IN BOTANY—The Secretary, The University, Aberdeen (January 20).

UNIVERSITY GRADUATE AS TEACHER OF ENGLISH for British-Peruvian Cultural Association, Lima—The British Council, 3 Hanover Street, W.1 (quoting 'Lima') (January 24).

LECTURER IN GEOGRAPHY in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2 (February 5).

LECTURER IN MECHANICAL ENGINEERING in the Witwatersrand Technical College, Johannesburg—Frank Ross and Co., 9 Fenchurch Avenue, E.C.3.

DIRECTION AND UTILIZATION OF RESEARCH

IT is not always realized that, when research in the laboratory has succeeded in producing a new article or product for manufacture, it is probable that a considerable amount of capital has to be spent—not only on plant, but also on overcoming engineering and chemical difficulties, and often in creating a demand for the product —before any return can be obtained. Under modern conditions one individual can rarely take all the steps required for the development of a new product—the research work, the design and running of the small-scale plant, the market investigations, the design of the full-scale plant, the building of the factory, the running of it, the management of labour, the control of output to meet the demand, the creation of demand, the actual selling and the finding of the capital to erect the plant and for trading. Most of these steps require specialists, and it could scarcely be expected that one man should have the knowledge to do them all well; if he had, it would be difficult for him to decide to which he should give his chief attention as the development proceeded.

Let us consider where and how research comes into the scheme of things. In the beginning, it is not usually obvious that a research reaching a successful conclusion is one suitable for development. Although a successful development may afterwards seem to have been very obvious, it was probably not so obvious at the time. There are always doubts as to the potentialities of the market, and even perhaps as to the availability of the raw materials at a cost which will leave a profit. A decision has to be made; a risk has to be taken. Hence the question of finance enters into the problem, for those responsible for finding the capital have to be persuaded that the risk is a reasonable one. This task is an important function of the 'director of research', and without him there are sure to be difficulties, misunderstandings, and perhaps in some cases recriminations. It is a matter of experience that the research worker who makes the discovery or devises the process is rarely the best person to win the necessary confidence of an administrative board.

It is of first-rate importance, therefore, to consider the qualifications of a successful director of research. First of all, he must be himself a scientific worker. He must understand the research workers' outlook; he must encourage their enthusiasms. On the other hand, he must have a keen appreciation of developments on which the administrative body is prepared to spend money. He must know as much as he can of all branches of the industry from manufacture to sales, or he will never be able to understand the outlook of the administrative board. His knowledge of science should enable him to have a broad idea of the lines on which the industry may be expected to develop, and he should continually keep the board and departmental managers informed of the lines on which he expects development to be made.

Although the director of research will not find much time for doing research himself, he must not allow administration to become his chief interest. He must believe in the scientific method of approach to a subject; he must be continually assisting in summarizing and relating the results of incompleted researches, and to do this he must have been a successful research worker himself. He should be a helpful critic of the researches of his staff.

While it may be conceded that an able director of research is needed in a commercial company to obtain the confidence of the administrative body for the development of scientific discoveries, it is not generally appreciated that directors of research of Government departments and research associations have similar tasks. There are now a considerable number of directors of research in Great Britain, and they have been an essential factor in the successes which science has achieved in industry and in the arts of peace and war. But the functions of these men are not generally understood by men of science, by Government departments, or by politicians, though these services are realized by many industrialists. Their services to science itself are rarely recognized, although some of them have been elected to the fellowship of the Royal Society before they became directors of research. It is generally impossible for the successful director of research to devote himself sufficiently to one subject, and in consequence this acknowledgment from the world of science rarely comes his way.

At the present time, when ministries and Government departments are being subjected to frequent scrutiny, it is opportune to recommend to them the inclusion of a director of research in their organizations. Some of the ministries have them, and probably would not be without them now. Others have scientific advisers who give advice when asked, but this is not what is required. Every ministry should have, as an integral part of its personnel, a director of research, in close touch with *all* its problems, whose principal duty would be to advise the ministry when the man of science can be helpful. The director of research would not, as a rule, attempt to give the scientific advice himself, but a small organization under his control would see that it was obtained from the best sources available, and, as further research would be needed in most cases, he would arrange for it to be done. The Ministry of Food should certainly have a director of research, and the Ministry of Agriculture too; he would enable these ministries to make fuller use of the Agricultural Research Council, and the Medical Research Council, as well as other research workers. Another department which might well have a director of research is the Board of Trade, to enable the Board to make use of the potentialities of the Department of Scientific and Industrial Research. Appointments such as these would add relatively little to the budgets of the departments concerned, but would go a long way towards ensuring efficiency in the utilization of the scientific resources of Great Britain.

DESIGN IN NATIONAL LIFE

The Shape of Things

An Introduction to Design in Everyday Life. By Noel Carrington. Pp. xv+209. (London: Ivor Nicholson and Watson, Ltd., 1939.) 6*s*. net.

A SUGGESTIVE chapter in Bavink's "Anatomy of Modern Science" is devoted to a discussion of the technological ideal of fitness for a purpose. Over an increasingly wide sphere of life we are becoming aware to-day that the squalor, ugliness and lack of beauty in our surroundings are due at least in part to the neglect of this principle. The deplorable position of the Special Areas can be directly attributed, as the successive reports of the commissioners for those areas show, to our lack of design in the planning of industry. The acuteness of the problems in the government of London can be traced to a like cause, and chaos in transport, ribbon building and the destruction of amenities have a similar origin in the absence of any comprehensive design sufficient to compel planning and control on an adequate scale.

It is not only in such matters that we have failed to utilize the possibilities which new materials and new means, put at our disposal by science, have afforded. In the smallest things of everyday life, the use of such materials or forces is apt to be determined less by their intrinsic qualities than by the traditional forms in which the materials they are superseding or displacing have found expression. Outstanding examples are to be found in the tardiness with which the motor-car has freed itself from forms imposed by the tradition of the horse-drawn vehicle, and the resistance of the building industry to the adoption of new forms and possibilities inherent in the steel framework or the new plastics.

Resistance or delay of this type is, however, not due entirely to the conservatism of the manufacturer. It is also partly due to the absence of a public awake to the possibilities and sufficiently alive to the fundamental principles of design to demand appropriate forms of expression for the new means and materials.

Mr. Carrington's little book has the great merit of giving in a very brief compass a comprehensive picture of the incidence of design in everyday life, from the ordinary utensils of house or office, houses, streets and vehicles to the larger problems of planning a city or a countryside. Much more is indeed being done than Mr. Carrington suggests to interest the general public in design, and he does not mention the distributor, the advances recently made in the education of salesmen, or the efforts of the Royal Society of Arts to raise the status of the artist in industry. Apart from such omissions, Mr. Carrington covers the field well, and the brief notes on books appended to most of the chapters contain numerous excellent suggestions for the guidance of those who wish to proceed further with any particular subject.

The appearance of the book is opportune even in war-time for two further reasons. In the first place, as Mr. Milner Gray has pointed out, industrial design is of the utmost national importance in the development of our export trade. If we are to maintain our position in the markets of the world which remain open to us, or to capture those to which Germany no longer has free access, the design of our export goods must be second to none. It will not be sufficient to produce the most obvious export goods under the rigorous conditions now existing. We must demonstrate that on top of meeting all our war-time needs, we also have capacity for quality production.

The importance of this to our economic position is obvious. If we cannot get loans, we can in this way obtain orders for goods, the making of which is as truly war work as any other. For this purpose the mere repetition of old patterns and shapes will not suffice. We have to show that our goods are not only better but also more attractive, and we shall have to make full use of all new good designs if the opportunity is not to be missed.

The second reason why Mr. Carrington's book is timely lies in the opportunities for improved design which should be ours in the reorganization and reconstruction which must be involved during and after the war. The profound disturbance of the fabric of our social, educational and business life under the demands of civil defence, no less than the adjustment of industry in general to meet the problems of supply or the reorientation of administration, whether in local or national affairs, present opportunities as well as problems. The present chaos in our physical surroundings persists less because we lack the knowledge of a remedy than because we lack the collective will to set things right. Not enough people have trained themselves to appreciate the nature of the problem. Scientific research and technique have far outstripped our ability to put them to proper use.

While the same principles inspire design wherever it operates, a wider cultural education is desirable if a sense of design is not to be departmentalism. This is indeed the gravest danger and the biggest obstacle to rational design in the larger matters of traffic problems or town planning and the like. A highly developed aptitude for design in a particular field may be accompanied by complete indifference to it either in the intimacy of the home or in civic or rural surroundings. The design so essential in our major collective enterprises can only be secured as individuals appreciating the value of design in some particular field are led to appreciate its importance everywhere.

Recognition of the place and value of design is indeed essential if the resources of modern science are to be utilized to rebuild our physical surroundings to serve adequately both our needs and our desires. One of the real tragedies of this age is that the divorce of the artist from the business of life has led to the great reconstruction which the machine age has necessitated being carried through without his aid. Only here and there are the new materials finding expression in new and more appropriate ways which satisfy not merely utility but also the æsthetic and creative sense.

There are indeed increasing signs that we are coming to recognize that the artist as designer is as essential a factor in our mechanized activities as he was in ancient Greece or any other period of history. If, however, in a few fields the opportunities which new materials offer for creative expression are being explored, the opportunities which are to be found in the planning of our cities, the development of transport, the preservation and development of the countryside are largely ignored. To awaken the mind of the ordinary citizen to these possibilities, to assist him to form an intelligent opinion upon them and to lend his support unhesitatingly and persistently to those seeking to use them is an urgent need, if those opportunities are not to be missed. In this task of education, leaders of art and industry with vision and creative force are imperative. Mr. Carrington's little book is well calculated to stimulate thought upon these larger issues, to facilitate the understanding which will assist the reintegration of the artist into society, and to inspire a concern for creative work which should enable us to build a nobler culture and a saner social order out of the chaos and destruction in which we are at present involved.

R. Brightman.

EARLY MAN IN UPPER EGYPT

Rock-Drawings of Southern Upper Egypt
1: Sir Robert Mond Desert Expedition, Season 1936–1937; Preliminary Report. By Hans A. Winkler. Pp. viii + 44 + 41 plates. (London: Egypt Exploration Society, and Oxford University Press, 1938.) 18*s*. net.

THE interest of the late Sir Robert Mond in the rock-drawings of the Egyptian desert was aroused by a collection of copies which had been made by Dr. Winkler in 1936; and with characteristic generosity and an equally characteristic ready appreciation of the possibilities of this line of research for the early history of man in Egypt, he undertook the responsibility for an expedition for the systematic study of the rock-drawings of Upper Egypt. In this preliminary report, Dr. Winkler summarizes and illustrates the results of his first season's work in 1936–37, dealing only with the most interesting and instructive examples, comprising about one tenth of his photographs. The material collected by the expedition has been deposited at the office of the Egypt Exploration Society, where it is available for consultation by students.

Of the possible methods of investigation, the author selected on this occasion the intensive study of a circumscribed area, choosing the country between Qena and Asswân. Most of the work has been carried out in the Eastern Desert between Quft and Qosêr, while in the Western Desert two small districts were worked near Armant, when Dr. Winkler enjoyed the advantage of being helped by members of an expedition of the Egyptian Exploration Society then excavating there.

The conditions in the two regions are markedly different. On the eastern bank of the Nile, profitable investigation was in the main confined to the sandstone formations of the Quft wadi-system, by which go the shortest routes to the Red Sea and the Sinaitic Peninsula. An old road with wells crosses the desert. On the west there are no such natural limitations. A seemingly endless limestone plateau borders the Nile, which is crossed by many roads. It is especially along such roads that rock-drawings are found; and, indeed, the presence of rock-drawings has sometimes indicated the existence of a road which had vanished. The author, however, draws a distinction. He points out that frequenters of the desert fall into two categories: those who are permanent inhabitants, such as the Beduin, and those who visit it as travellers. This distinction applies no less to early than to modern times, with the result that while drawings by travellers from the Nile valley as well as drawings by desert tribesmen are found along the lines of the roads, the drawings of the desert peoples may also be found anywhere in the desert.

Forty sites were visited. The subjects of the drawings are of a greatly varied character, ranging from purely geometrical signs to relatively realistic figures of men and animals. Boats of more than one type are plentifully represented—in fact, more plentifully than in any other group of rock-drawings, with the possible exception of Scandinavia. One rock painting only was discovered. This was in the Eastern Desert. It represents a man (dark red), archer (light red), ibex, and another animal (brown). It shows no artistic sense and its date is uncertain.

A proportion of the petroglyphs can be classified on adequate grounds as modern or ancient Arab, while others belong to either the Græco-Roman-Coptic period or the Dynastic. The majority of those of the Græco-Roman-Coptic period are assigned to the people known in antiquity as the Blemyans, a desert people, who rose to ascendency in the period from the third to the sixth century of our era. With them the camel appears for the first time in desert drawings; and its use was, no doubt, at the root of their political and economic domination.

The greater number of the drawings, however, cannot be dated with this certainty; and the conclusion as to their age rests upon the character of the drawings themselves and attendant conditions—position, superposition, patination, archæological finds, and the like. They are classified as Early, Pre-dynastic, and Prehistoric. Dr. Winkler assigns them to four distinct ethnic groups, for whom he has worked out a relative chronology.

These groups are as follows: (1) Autochthonous Mountain People, Hamites and cattle-breeders, who lived not only in the Eastern Desert, but also penetrated deeply into the Western Desert. The men wore the Libyan sheath. They may be regarded as the ancestors of the Blemyans. They appear to have outlived the elephant and giraffe, and probably introduced cattle into this region. (2) Early Nile Valley Dwellers, with boats showing affinities with those appearing on pre-dynastic pottery. This people was an intrusion from the Nile, and lasted down to dynastic times. (3) Eastern Invaders, a people previously almost unknown. They appear with boats of a foreign type, first recognized as such in Dr. Winkler's expedition of 1936. The boat, though a proof of early Mesopotamian influence, is probably of other, but unidentified, origin. This people is contemporary with elephant and giraffe, and was in contact with both Mountain Dwellers and the Nile Valley people. They did not penetrate the Western Desert. (4) Earliest Hunters, whose discovery must be placed to the credit of this expedition. They hunted elephant and giraffe, and are represented in both the Eastern and the Western Desert.

Though no specimens of the common type of Libyan sheath-wearing peoples have been found adjacent to the river on the western bank of the Nile, parallels to the older wedge-style of the Libyan sheath wearer, but with not unimportant differences, are known from the distant 'Uweinât' and elsewhere in the Libyan desert. At the same time, it is to be noted that the author claims a possible Hamitic origin for a group of drawings on the west side of and near the Nile, otherwise remarkable as the only example in the whole collection which can be called a work of art. An appendix deals with the characters of the boats and their relation to other representations of boats in early Egypt and Mesopotamia.

Dr. Winkler displays great acumen and powers of observation in his interpretation of these drawings as indications of the respective material culture, social organization and religious beliefs of his four ethnic groups. He is to be congratulated on the successful result of his investigations; and the continuation of a study which promises to throw so much light on the movements and cultures of the early peoples of these regions will be awaited eagerly.

MECHANICAL ANALYSIS OF SEDIMENTS

Manual of Sedimentary Petrography
1. Sampling, Preparation for Analysis, Mechanical Analysis, and Statistical Analysis, by W. C. Krumbein; 2. Shape Analysis, Mineralogical Analysis, Chemical Analysis, and Mass Properties, by F. J. Pettijohn. (Century Earth Science Series.) Pp. xiv+549. (New York and London: D. Appleton-Century Co., Inc., 1938.) 30*s*. net.

This interesting book is divided into two portions: the first by Krumbein deals with size determination of sedimentary particles, and the second part, by Pettijohn, is largely concerned with the optical properties of minerals. All who are interested in sediments will find this book most useful, as it contains descriptions of various techniques and methods of interpretation.

Krumbein, after discussing the collection of samples, suggests methods for the preparation of stable suspensions. One chapter is devoted to grade scales, and the advantages of a geometrical scale are pointed out. A theoretical discussion on the principles of size analysis follows, and those who are unacquainted with this subject will find a clear and adequate explanation. Although there is a wide choice of methods available for mechanical analysis, the present tendency is to use mechanically operated sieves for particles greater than 50μ, and the pipette method for smaller particles. For accurate work elutriation methods find to-day little favour in sedimentary laboratories. The pipette method is described in detail, but the accuracy of this method is not discussed. It would seem, however, important that the investigator should not only realize the experimental errors, but should also carry out occasional duplicate analyses, preferably adopting a slightly different technique. Only one page is devoted to the application of centrifugal force to mechanical analysis; a method which is most useful in fine-grained sediments.

The remainder of Part 1 is largely concerned with graphic presentation of results. Histograms, cumulative curves, frequency curves are described, as well as the elements of statistical analysis. The reader will find a clear and non-mathematical introduction to quartile measures, moment measures, measures of central tendency, of dispersion, skewness and kurtosis. Finally, some special statistical methods are briefly described and a discussion is given concerning the choice of statistical devices.

To the mineralogist Part 2 of this book is not very important, as optical methods of identification have been frequently described, but to the non-mineralogical student the inclusion of this portion will be useful. The procedure for analysis of shape and roundness is also discussed, as well as methods for mineralogical separations; but chemical methods of investigation are limited to five pages.

The book as a whole can be thoroughly recommended, and the authors are to be congratulated on collecting together from many sources a large amount of information, and thereby making it more readily accessible. J. D. H. W.

FOUNDATIONS AND DEVELOPMENT OF HEAT

A Text-Book of Heat
By Prof. H. S. Allen and R. S. Maxwell. Part 1. Pp. ix + 527 + xvi. 10*s*. Part 2. Pp. x + 531 – 849 + xi. 10*s*. 6*d*. (London : Macmillan and Co., Ltd., 1939.)

RECENT years have seen the production of several books on heat such as Roberts's "Heat and Thermodynamics" and Saha and Srivastava's "Treatise on Heat", to say nothing of more special works such as Hoare's "Thermodynamics". But the work now before us occupies a place of its own and will be welcomed by teachers who wish for something between an elementary text-book and a comprehensive treatise. It gives the best of the earlier work and at the same time includes some account of recent investigations.

The authors emphasize the fact that they treat the subject from the historical point of view, and there are full accounts of fundamental experiments by Joule and others, quotations from authorities, and many biographical notes. But while this undoubtedly makes the subject more interesting, there is little difference between the order of historical development and that of logical development, and the historical treatment does not impress the reader so much as the easy and gradual way the student is led into the subject.

There are two contrasting ways of writing a text-book of physics. One way is to give clear, concise statements suitable for reproduction in an examination and not going much beyond the range of the examination ; the other is to proceed by degrees, to build up a mental picture of every equation and to make the accounts of the experiments as full as possible. This is pre-eminently the method of the authors of this book and the reason for its 849 + xlvi pages. They read very easily because every chapter is obviously the result of teaching experience. After reading and understanding a book such as this, the average student is able to make his own synopsis of the subject, whereas if the concise statement were thrust at him at first, he might make nothing of it. It is, of course, for the student of physics the book is written ; the mathematical honours man may wish to travel faster.

Part 1 is intended for students preparing for the Higher School Certificate or Intermediate Examination in physics or for a university scholarship. The calculus is used occasionally, but the mathematical treatment is very simple. Part 2 is intended to meet the requirements of those reading for a pass degree in physics and to furnish a foundation for an honours course.

Near the beginning of Part 1 we notice the customary account of Davy's experiment on rubbing the plates of ice together. Prof. E. N. da C. Andrade (NATURE, 135, 359 ; 1935) has some hard things to say about this experiment. It was carried out when Davy was a country lad of nineteen years of age. If the ice is covered with a film of water, the friction is so small that scarcely any work is done at all, whereas if it is really dry it is liable to stick. To make the frictional heat appreciable it is necessary to have a normal force holding the two surfaces together, and then there is the well-known lowering of the freezing point and consequent melting. Again, the amount of heat required to melt 1 gm. of ice is very large ; the criterion is a very insensitive one, and no one has ever tried to repeat the experiment. The effect was due to conduction, and the experiment should cease to rank with such a convincing demonstration as that of Rumford. The customary account of the experiment must be allowed to stand in the old text-books ; but in view of these statements something different is called for in a new one.

In a book written as a text-book for definite examinations, it is not possible to be very original, and Part 1 develops on conventional lines. Everything that could possibly be asked for in the examination is given ; this is saying a lot, because examiners in physics do not keep to well-defined curricula, which makes it anything but a safe subject in Civil Service and other examinations. There are also questions from the examination papers of different British universities, with the answers.

But while this first volume is, generally speaking, on conventional lines, some things such as the steam and internal combustion engines, the liquefaction of gases, etc., are done unusually well, and the last three chapters, which deal with meteorology and the dimensions of thermal quantities, are an interesting innovation. We note in passing that the theory of the experiment of Clément and Desormes is given and that it is followed by the statement that the experiment does not work ; but we are not told definitely that Gay-Lussac and Welter's modification of the experiment is any better.

Part 2 gives more scope for originality of treatment. The first half of the book is thermodynamics, but thermodynamics treated from the experimental point of view, which makes it easier to assimilate. The experimental physicist will, of course, object to the chapter on thermodynamic functions and relations, but this is inevitable. Then after an account of the approach to the absolute zero, which includes the paramagnetic method and a full account of Nernst's heat theorem, there are accounts of the mathematical theory of conduction, convection, the measurement of radiation, the quantum theory and the modern theory of the specific heat of solids. The last thirty-five pages deal with statistical mechanics, the Bose-Einstein statistics and the Fermi-Dirac statistics each receiving a couple of pages. Larmor's indirect pressure theorem is a welcome innovation. The simplest definition of entropy is omitted, namely, that the increase of entropy of a substance multiplied by any low temperature gives the increase of unavailable energy of the substance with reference to that temperature, and there is no description of the photo-electric rectifier cell in the chapter on the measurement of radiation. It is difficult nowadays to say where heat stops and electricity begins, but we think this instrument ought to have been included. These are minor points.

The space given to statistical mechanics and probability is undoubtedly a move in the right direction. These concepts are becoming very important for the purpose of understanding the world around us. But it is not easy to write an account of them for the average student.

Altogether the work is a notable addition to the text-books on heat. It is the work of practised teachers and is written with great care. It is alive with modern information and research; besides being a text-book it is a storehouse of information, reference to which is greatly facilitated by the excellent indexes at the end of each volume. Much of this information the student will find unnecessary, but it will serve as a background to his knowledge and perhaps as a basis for research. The type and paper are excellent.

R. A. Houstoun.

SYSTEMATICS OF MILLIPEDES

Myriapoda 3, Polydesmoidea II, Fam. Leptodesmidæ, Platyrhachidæ, Oxydesmidæ, Gomphodesmidæ

Bearbeitet von Dr. Graf Attems. (Das Tierreich: eine Zusammenstellung und Kennzeichnung der rezenten Tierformen. Im Auftrage der Preussischen Akademie der Wissenschaften zu Berlin. Herausgegeben von F. E. Schulze, W. Kükenthal, K. Heider, fortgesetzt von R. Hesse. Lieferung 69.) Pp. xxviii + 487. (Berlin und Leipzig: Walter de Gruyter und Co., 1938.) 81·25 gold marks.

Any work on the Polydesmoidea from the pen of Count von Attems must command repsect. His contributions to our knowledge of a taxonomically difficult group have been very numerous and he is of course well fitted for the task of drawing together the threads of description and weaving them into a serviceable whole. The volume under notice begins with a list of works of reference occupying ten pages, and similar space is devoted to a clear and very useful systematic index. The author then plunges into the real business in hand to give nomenclatural particulars and full descriptions of the families mentioned in the title and to deal with all their subdivisions down to subspecies and varieties. It is a formidable task, for more than eight hundred species, certain and uncertain, need consideration.

In the nomenclatural jungles where Chondrodesmus, Allarithmus and Phlyzakium roam there are pitfalls for the wary as well as for those less careful. Even specialists find the name of Platyrhacus (a genus with more than 180 described species) difficult to spell. Since C. L. Koch first used the name in 1847, it has also been Platyrhachus, Platyrhachis, Platyrrhachus, Platyrrhacus, Platyrrachus, Platyrachus and Platyracus, but we seem to have got it right at last. Not so the family appellation, for here even Attems himself goes astray with Platyrhachidæ, a name that appears both on the cover and title page of his work.

In his description of colours, Attems meets a difficulty most naturalists encounter. Until some general colour standard is adopted it seems best to decide upon the fundamental colour 'brown', 'yellow', 'black' or whatever it may be and then to add adverbial modification where this is necessary.

In spite of the thorough treatment adopted by Dr. Attems, there is a sense of disappointment with the way in which this expensive work is illustrated. Figures that are of great value for taxonomic purposes are liberally included, they are admirably clear in spite of the variety of their sources, and the lettering is excellent, but there is no adequate reminder that we are really dealing with living animals and that it is, after all, a branch of natural history that is under consideration. We go back in mind nearly eighty years to H. de Saussure's paper on the myriapods of Mexico. To look at those wonderful plates was to realize that millipedes are really alive, and it gives the naturalist a sense of satisfaction for which the scientific accuracy of the present day is no real substitute. We want both kinds of illustration; at least a few figures of the old kind to cheer the pages and make them less dull, and to take away the impression that we are dealing with nothing but dried specimens in a museum collection and that the subject is a drab one. *Eutheatus erythropygos* (Brandt, 1841) is a good example because it is on de Saussure's first plate. Attems gives us a neat little figure (after Carl) of the gonopod, and very useful it is; but how much more satisfactory it would have been if we could have had de Saussure's delightful drawing of the whole animal reproduced as well. When no figure of the gonopods is available, it is still more to be deplored that no such illustration as that given by de Saussure is included by Attems. An instance of this is provided by *Rhysodesmus zapotecus* (Sauss.); de Saussure admirably depicts the whole animal.

Sometimes the treatment adopted by Attems is difficult to understand. Take *Platyrhacus* (*Tirodesmus*) *mexicanus* (Lucas); although Attems gives no description, this species is fully described and segments figured by de Saussure. Of the species *P*(*T*) *bilineatus* (Lucas) which de Saussure regards as near *P*(*T*) *mexicanus*, Attems gives a full description with one figure (side-view of gonopod).

When all is said, however, and we come to the end of a series of minor criticisms, we feel that Count Attems has done systematists a great service. More power to his pen!

S. GRAHAM BRADE-BIRKS.

GEOLOGY OF INDIA

Geology of India

By D. N. Wadia. Second edition. Pp. xx+460+20 plates. (London: Macmillan and Co., Ltd., 1939.) 24*s*. net.

THIS book, which from its first appearance has been the standard text-book of Indian students, has now been brought up to date by the addition of recent advances in Indian geology. The new geological map is an added attraction.

The revision has not, however, been sufficiently far-reaching and thorough. As a result, a novice to the subject of Indian geology will occasionally be puzzled by finding both the old and the modern view stated without due explanation.

The Salt-Range is regarded (p. 104 and Fig. 8) as a block-faulted structure, but later in the book we are told that over-thrust faulting is a marked structural feature.

On pp. 146 and 147, it is noted that the Upper Gondwanas of the Madras coast and probably the Rajmahal beds also must now be regarded as Lower Cretaceous and not as Jurassic. These recent conclusions—the work of Dr. Spath and Prof. Sahni—should have caused a more extensive revision of the whole subject, including alterations in the tables on pp. 51 and 130.

In the table of the Siwalik stages on p. 271, the views of Dr. Pilgrim as to age are given. But in a later table on p. 280 we find an entirely different view of the ages put forward by Dr. de Terra. An explanatory note was here called for.

Before writing his account of the Bagh Beds and the "Cenomanian Transgression" (p. 206), Mr. Wadia would have done well to have studied the views of Dr. Spath on the subject (*Pal. Ind.*, New Ser. **15**, Part 5, 64).

The account of the Samana section and the Hangu Shale fauna is too brief in view of its importance (see p. 246).

Perhaps the most disappointing chapters are those dealing with the Indian pre-Cambrian. There is no basis for the separation of the Himalayan pre-Cambrian into Archæan and Algonkian, as is attempted on pp. 81 and 99, and, as the age of the supposed Burmese pre-Cambrian is even more doubtful, it was not correct to place the Mergui series in the Archæan (p. 54).

Considering the great advance made in the study of the Peninsular pre-Cambrian by the Indian and Mysore Geological Surveys of recent years, the account is meagre and not free from intermixture of old and new views (for example, age of Bundelkhand gneiss on pp. 62, 63 and 73). The modern correlation of these rocks should have been given, and the views of M. S. Krishnan (Twenty-second Indian Science Congress, 1935), which admirably express the general opinions of the staff of the Indian Geological Survey, might have been studied.

In short, the entire rewriting of these chapters, and of that dealing with the Upper Gondwanas, would have improved the book. Nevertheless there is much valuable new material, especially regarding the Salt-Range, North-West India, and Kashmir. The structure of the Himalaya—the results of the work of West, Auden and Wadia himself—is excellently summarized in Chapter xxv. Those portions dealing with marine fossiliferous rocks and with economics are also of a high standard, and, in spite of such defects as those noted above, Mr. Wadia is to be congratulated on his new edition.

G. DE P. COTTER.

ERNST ABBE (1840-1905)

THE ORIGIN OF A GREAT OPTICAL INDUSTRY

THE great optical works of Zeiss in Jena, employing round about ten thousand people, is one of the leading firms of the world in the production of fine optical apparatus. This firm owes its high scientific standard, its economic efficiency and its growth to the creative genius of Ernst Abbe. The optical works of Carl Zeiss were originally the workshop of a skilful mechanic producing the necessary equipment for the laboratories of a small provincial university. The scholar Abbe gave to the mechanic Zeiss the results of his original scientific research. This was then leading to new methods in the design of optical apparatus, especially of microscopes. Those new instruments were of extraordinary perfection, so that an enormous demand from every part of the world made possible an extremely rapid expansion of the business. When after twenty years of growth, the well-known company had developed, Abbe renounced all his rights and gave the firm of Zeiss a constitution which has enabled it to survive its creator and to continue into our own turbulent times.

Ernst Abbe was born on January 23, 1840, as the eldest child of a poor workman. It was beyond the means of his father to provide a higher education for him. The boy started in an elementary school. Later, the generosity of the employers of the father secured a scholarship at a higher school for the boy, who early showed signs of an unusual intelligence.

In 1857, Abbe began his studies in Jena, which was at that time still a small town with a population of less than seven thousand. Jena was living then in idyllic isolation from the great world ; no railway touched it. The university was incredibly small. Its faculty of science consisted of three professors only, who were paid an average salary of £30 a year. Abbe studied in poverty ; his father could provide very little for him. He augmented his income by giving private lessons. It is not surprising that he had to live in the cheapest quarters, and it was no unusual event for him to replace a hearty meal by a pipe of tobacco. But in spite of all hardships, the two years in Jena meant a happy time for Abbe, who there acquired a knowledge of the fundamentals of the mathematical and physical sciences.

In 1859 Abbe continued his studies in Göttingen. He left Göttingen in 1861 with a Ph.D. The next two years were spent as lecturer to a private physical association in Frankfort. Although this engagement for popularizing science was not to the taste of a personality like Abbe, it brought him social contacts which proved to be important. When, in 1863, he was admitted as an unpaid lecturer at the University of Jena, a rich merchant of Frankfort enabled him to start his academic career by a personal grant sufficient to cover all his initial expenses. During his early years Abbe was kept busy with running practical classes and with preparing and delivering lectures. This was the beginning of his activity as a university teacher, which was destined to last for thirty-five years until 1898. He became associate professor in 1870 and full professor in 1878. He refused the most tempting offers of appointments in other universities, and spent the whole of his time in Jena. During the course of time he gradually dropped his mathematical lectures, specializing more and more in physics and eventually in optics only. His last lectures were of the widest interest, and were attended by the staff of his industrial co-operators and by distinguished scholars from all over Germany. From his early years he was closely attached to the professor of physics, K. Snell, whose daughter Elise he married in 1871.

While still a young lecturer, in 1866, Abbe came in close contact with Carl Zeiss. The little workshop of Zeiss was then successfully producing simple microscopes which could well compete with other instruments of this kind. All these microscopes were made according to a practical tradition developed by empirical methods. Abbe was the first to introduce scientific methods and systematic design. He recognized that the magnification of an even ideally corrected microscope was limited. There were no prospects whatsoever of resolving optically two parts of an object separated by less than about half the wavelength of the illuminating light, that is, about 0·0003 mm. This is of the greatest importance, because it indicates clearly that the only possible way of developing the microscope was by elimination of the optical errors within the limitation of reasonable magnification. Two lines of attack were available : first, the geometrical shape and the arrangement of the refracting lenses ; secondly, their physical properties, that is, their refraction and dispersion. Abbe made fundamental progress in both directions. His new results were at once applied in the optical workshops of Zeiss.

The new microscopes were far better than anything on the market, and thus the business of Zeiss's workshop expanded rapidly. Soon after (in 1876), the sale of the three thousandth microscope was celebrated, and in the same year a contract was concluded making Abbe an equal partner in the business. The glass sorts which were commercially available and which Zeiss used as a raw material were very much alike. Abbe tried to interest leading glass manufacturers in the production of new glass sorts with different optical characteristics. The small quantities of glass consumed in the microscope industries, however, did not guarantee a reward for these expensive experiments. In an interesting lecture during the London international exhibition in 1876, Abbe tried to interest scientific societies in his problem, but he was unsuccessful.

Abbe's appeal, however, was taken up by a young glass manufacturer, O. Schott, who was able to see beyond the immediate small practical prospects towards the great scientific and technical importance of the problem. Schott's father owned a small factory producing plate-glass in eastern Germany. Abbe persuaded Schott to move to Jena and to start a glass technical laboratory with him. New glass sorts—especially borate and phosphate glasses—were developed there, opening up new prospects for the optical industry. From this laboratory arose the famous Jena glassworks. In 1884 these glass works were started with twelve employees; the Ministry of Finance of the State of Prussia secured a subvention for the first two years. In the years which followed, the Zeiss works took up the manufacture of all kinds of optical gear, including, besides microscopes and telescopes, fine photographic objectives, prism-telescopes, telecomparators and periscopes, which are all produced in relatively large quantities. Of more specialist interest is a large number of types of other apparatus which were originally designed by Abbe, for example, spectrometers, refractometers, spherometers, apertometers and many more.

In the meantime, the firm of Zeiss expanded year by year. In 1899, a thousand workers were employed. At the time of Abbe's death in 1905, the number of 1,500 employees was passed. Before the War of 1914–18, six thousand employees were engaged in the works. Owing to the heavy demands for optical gear for war purposes, this number increased temporarily to nearly ten thousand, but it dropped to a half this number immediately after the War. Since then, the number of employees has gradually increased again, and to-day it has probably passed the former peak-level.

Of Abbe's scientific papers his discussion on image production in microscopes is still of great interest. At the age of twenty-eight, he formulated his famous sine law. A few years later, in a fundamental theory, he demonstrated the connexion of the projection of optical images with the diffraction of light waves. According to his theory, the aperture of the microscopic objective has to be large enough to collect an essential part of the diffraction pattern.

It is remarkable how quickly Abbe's discoveries became known in England. He was in the closest contact with English men of science—Crisp, Mayall, Wenham, Lettsom and Stephenson. A correspondence of more than a thousand letters with these English friends is preserved. All of them showed the greatest affection and admiration for Abbe. Stephenson wrote of him:

> "Objectives and their laws lay hid in night,
> God said: 'Let Abbe be, and all was light.'"

Abbe had worked for fifteen years managing and directing the great optical firm when, in 1891, he gave it its well-known constitution. He renounced all his property rights, making himself an employee of the great organization. The fact that one of the statutes of the constitution limits the maximum salaries in this firm to ten times the amount of the minimum wage paid, shows that the remuneration of the directors cannot be excessive. The Zeiss Institution is registered as the legal owner of the company, no shares being issued. Care and custody of the Institution is entrusted to the Ministry of Education of the country. The undertaking, however, is not subject to the control of the Government administrator, but solely to the provisions of the charter, and the function of the official administrator is to see that these provisions are carried out. The works are controlled by a board of three or four directors who have to be elected by the Minister of Education from the scientific staff and from the technical and administrative employees of the company. All the earned income is received and distributed by the Zeiss Institution. In these circumstances, the employees enjoy extraordinary benefits and their health and social welfare are first considerations.

Abbe was a true Christian, though he was not a member of any official church, and, declaring himself a dissenter, he even avoided any contact with organized religion. In opposition to many relatives and to his father-in-law, he refused the religious ceremony for his marriage and the christening of his two daughters. Politically, Abbe may be called a liberal; he joined in his later years a liberal democratic party. He disliked any extreme nationalism; he was known even to be in opposition to the policy of Bismarck. Any racial prejudice of 'blood and soil' was quite alien to his mind. His closest co-operator and friend, S. Czapski, whom he chose as his successor in leading the great organization, was of purely Jewish descent.

Later in life, Abbe suffered from insomnia, which he tried to overcome by an excessive use of drugs. In the end his nervous system showed all the signs of exhaustion and at the early age of sixty-three he had to retire. Two years later, in 1905, he died from pneumonia.

It will be widely agreed that the firm of Carl Zeiss occupies the first place among the optical firms of the world. This distinction is merited on the ground of the size of the firm and the variety of its products, coupled with the general excellence of its work. Its reputation for many years has been so high as to have given rise to a superstition that any Zeiss instrument is better than a corresponding instrument made by any other firm. In passing, it should be said that this superstition has many adherents in Great Britain, though it is unquestionably and inevitably false. Just as other firms have imitated Zeiss instruments, so a number of the finest Zeiss products are more or less copies of designs introduced by other manufacturers; indeed, the firm makes a special point of knowing exactly what its rivals are producing, and to this end makes a practice of purchasing on the open market a sample of all new designs of optical instruments. But the fact that the lead in particular instruments changes at times from one maker to another in no way detracts from the many valuable contributions made by Zeiss to the progress of optical science.

The foundations of the firm's greatness were laid by Abbe. Its reputation in the first place was built on the notable improvements he introduced in the microscope. It is interesting to note that from the beginning he followed the plan, which has since proved so valuable to the firm, of publishing papers in scientific journals.

Abbe's theory of image formation in the microscope has been of great assistance to large numbers of microscopists, though many physicists find Rayleigh's treatment of the subject more fundamental and convincing. Among the new glasses produced in an endeavour to secure better microscopic images were some which led to greatly improved photographic lenses—the anastigmats—Zeiss being one of a number of firms to bring out new designs at about the same time.

Although these new instruments were calculated trigonometrically on lines laid down by Abbe, whose aim was to use computers with limited mathematical knowledge, the problems involved were considered in a general way in a treatise planned by S. Czapski. This and a number of later volumes, notably those due to M. von Rohr, are among the best modern works on optics and have added to the prestige of the firm.

The prosperity of Zeiss to-day is in no small measure due to the form of control set up by Abbe—there are no shareholders and no family claims, so that it has always been possible to secure the finest machine equipment as well as to advertise effectively, and to select able men for responsible posts. The great size of the business, which in part was brought about by the large continuous demand for military instruments for the German Army, has enabled research and development to be carried out on a scale impossible in much smaller businesses. By way of illustration, the firm studied the problems that would be presented if maps were to be prepared from photographs. The outcome was the construction of a series of instruments, used to-day in several countries, for mapping from aerial photographs. Some of these instruments are of extreme complexity; despite their great interest and the ingenuity shown in their construction, they have found less favour in Great Britain than in other countries. As another example, possibly built largely for their advertising value, the Zeiss planetaria may be mentioned.

In recent years the firm of Zeiss has built a number of beautifully designed and made instruments of great value to engineers in setting up difficult work accurately, and in other ways. A number of laboratory instruments has also been marketed, but some of these show a tendency which ought to be discouraged. Instead of measurements being recorded on scales which can be defined apart from the instrument, readings are obtained which must be compared with others made on the same type of instrument. Apparently conversion to values obtained in other ways can only be made if the Zeiss apparatus is purchased to experiment with. This course appears to have been adopted deliberately: it tends to create a closed market for instruments in fields where one or two leading investigations have been carried out with Zeiss apparatus. The remedy is clearly in the hands of scientific workers.

This note must not close without reference to the equipment made for ophthalmic opticians and to the firm's spectacle lenses. Apart from such special products as contact lenses and cataract lenses, the Punktal series of lenses is designed to give the best possible vision over a large field with the most varied kinds of visual correction. This is a service of great humanitarian value. The moderate price of these lenses, which are highly finished, shows that the firm can manufacture a wide variety of aspherical surfaces with good accuracy by mass-production methods.

CARBON MONOXIDE AS A HAZARD OF POLAR EXPLORATION

BY PROF. YANDELL HENDERSON AND J. McCULLOUGH TURNER, YALE UNIVERSITY

PETER FREUCHEN, speaking from his long experience in the Arctic, has said recently that "only when modern times came in did the exploration of the Polar regions begin to amount to anything real. The invention of the Primus stove did more than anything else. After that came the dog sledge." Certainly modern polar explorers have a great advantage in the hot food and ample supply of drinking water that the Primus stove affords.

THE PRIMUS STOVE AND NANSEN COOKER

Shackleton, in describing the outfitting of his expedition to the Antarctic, says, "a vitally important article of the equipment for the Polar explorer is the cooker and cooking stove. Here again we are indebted to the practical genius of Nansen, who designed the form of cooker that is now invariably used in Polar work. The stove was the ordinary 'Primus' burning kerosene vaporized in the usual way. This stove is highly efficient and with strict economy one gallon of oil will last three men for ten days, allowing three hot meals per day. This economy is due in a large measure to the qualities of the cooker. The form we used consisted of an outer covering of aluminium drawn out of one piece, inside which was a ring-shaped vessel so designed that the heated air could circulate around it. Inside this vessel was the centre cooking pot, and these pots were all mounted on a concave plate of aluminium which fitted over the top of the Primus lamp. The middle cooker was first filled with snow or ice, pressed tightly down, the lid was put on and this vessel placed inside the outer, ring-shaped cooker, which was also filled with snow ; over all this apparatus the aluminium outside cover was placed, inverted. The heated gases from the stove, after heating the bottom of the centre cooker, mounted into the space between the two vessels and then were forced down the outside of the ring-shaped cooker by the cover, finally escaping at the lower edge. Experiments showed that about 92 per cent of the heat generated by the lamp was used in the cooker, a most satisfactory result, for economy in fuel is of great importance when the oil has to be carried on sledges. . . . Such was the efficiency of the cooker and the stove that, in a temperature of 40 or 50 degrees below zero, the snow or ice, which would be at this temperature, could be melted and a hot meal prepared within half an hour from the time the cooker was first placed on the Primus. The whole apparatus, including the Primus, did not weigh more than 15 pounds."

Such are the advantages of the Primus stove and Nansen cooker. It has only recently been realized that in this combination lurks a danger—that of asphyxiation by carbon monoxide—greater perhaps than any other to which modern arctic explorers are now exposed.

Beside the fatalities, which leave no witness, there have been several narrow escapes. Amundsen was once near death from asphyxiation during his exploration of the North-East Passage. Byrd has recently published an account of how near he came to collapse from a badly adjusted kerosene stove ; but in his case fumes additional to carbon monoxide were also involved. Stefansson has now focused attention on this hazard and its insidiousness. He reports that, in a snow house that became iced and impervious to gases, one of his Eskimo companions "all at once threw himself backward upon the bed. I asked Anderson to see what Tannaumirk was up to—and Anderson fell face forward on top of Tannaumirk. I extinguished the Primus stove. Natkusiak broke away the loose block of snow by which we had a few minutes before closed up the door. He then crawled outside on all fours, but was too weak to stand up. I followed him out and had strength enough to stand up. But that was only for a moment and I fell down beside Natkusiak." Fifteen minutes after the door was opened, Anderson crawled out and after another ten minutes, Tannaumirk, "but neither had any realization of what had happened." An hour later three of the party were well enough to go into the house again, but "Tannaumirk was ill throughout the night and into the next day". All the features of this adventure—including the collapse on reaching fresh air—are characteristic of partial asphyxiation and justify Stefansson in referring to it as "the narrowest escape from death we had on our whole expedition".

With this experience in mind Stefansson, in his "Unsolved Mysteries of the Arctic", has discussed the question, "How did Andrée die ?": and has marshalled the evidence suggesting that that intrepid explorer, and at least one of his two companions, died of carbon monoxide asphyxia. The tragedy, as told in "Andrée's Story", the official account published by the Swedish Society for Anthropology and Geography, was briefly as follows: On July 11, 1897, after several years of careful preparation Andrée and two companions, Strindberg and Fraenkel, embarked from Spitsbergen in a balloon and floated away over the Arctic sea. Their object was, if possible, to get close enough to the North Pole to permit them to land on the ice and walk back to the coast. For that part of the expedition they were fully equipped.

They disappeared for thirty-three years. Then, in the summer of 1930, by pure chance, their remains were found on White Island, a bit of land between Spitsbergen and the Franz Joseph Islands. Enough of their records were salvaged and later deciphered to show that, although they had not attained the Pole, all else had gone essentially as planned until, on their return journey, White Island was reached. There, in some unexplained manner, Strindberg lost his life and was buried; and a day or two later Andrée and Fraenkel appear to have died peacefully in their tent.

Carbon monoxide is believed by Stefansson, Pallin, Sverdrup and others to have been responsible for two of the deaths. The Swedish committee, on the contrary, even after the most thorough investigation, has not felt justified in adopting this hypothesis. A critical piece of evidence is lacking; it concerns the Primus stove.

The Primus stove which Andrée and his companions used, was found in good condition and still contained some fuel. But it is uncertain whether the pressure-release valve was open or closed. In carbon monoxide asphyxia, muscular control fails when the blood is about 50 per cent saturated with the gas; unconsciousness occurs at about 60 per cent saturation; and death at 75–80 per cent. If then this valve was open, the explorers must have been still conscious and able to move; and their blood was probably not more than 40–50 per cent saturated with carbon monoxide, when they turned this valve and extinguished the flame. In that case even a slight leak of air in and out of the tent or snowhouse would have prevented asphyxiation. If, on the contrary, the valve was still closed when the stove was found, they must have neglected to turn the valve, release the pressure in the stove, and extinguish the flame. The Primus then continued to produce carbon monoxide, until the gradual fall of pressure in its reservoir and cessation of the flow of kerosene extinguished the flame. But before that occurred, the blood of the explorers became 75–80 per cent saturated with that gas; and they died. The question will probably remain for ever undecided.

CONDITIONS FOR PRODUCTION OF CARBON MONOXIDE

Whatever the fate of Andrée and his companions may have been, it is important for future explorers to know whether a Primus stove, with vessels above it for cooking and for melting ice, arranged as that of Andrée was, is capable of producing, within one or two hours, sufficient carbon monoxide to render the atmosphere of a small tent or hut lethal, and whether the arrangement may not be altered so as to eliminate this hazard. This we have attempted to determine.

The Primus, although it consumes liquid fuel, is essentially a gas stove. Like other gas stoves, it may produce carbon monoxide in any one or two or all of three ways. If the supply of air to the flame is inadequate for complete combustion, or if the draught in a flue above the flame is insufficient to carry off all the products of combustion, some of the carbonaceous substances in the gas are oxidized only to carbon monoxide, instead of carbon dioxide. The other mode of production of carbon monoxide is not so generally realized, although it is probably quite as common. It occurs whenever a tea kettle is heated over a gas ring with a fairly large flame. That part of the flame which impinges upon the kettle or other vessel is cooled below the temperature requisite for complete combustion; and carbon monoxide is formed and escapes. Similarly in gas water-heaters in which the flame plays upon a coil of metal pipe through which the water flows, dangerous amounts of carbon monoxide may be formed. For the health of our cooks, even if on a given consumption of gas the kettle heats more slowly, the rack on which the kettle rests should support it 2–3 centimetres higher than is common now and just above the flame, instead of in it. For safety all gas heaters should have flues.

Mere inspection of the diagrams of the Primus stove and Nansen cooker in Nansen's "Farthest North", "Andrée's Story" and other books of polar exploration is sufficient to raise a suspicion that one or even all these conditions for the production of carbon monoxide have vitiated their cooking apparatus. The access of air is not entirely free. The passage through which the burned gas must pass is long and for half its length is against gravity; and the Primus appears to be held so close below the central cooking vessel that a considerable part of the flame impinges upon the vessel.

For the analysis and improvement of these conditions the first question to be decided is whether the stove itself is responsible for a production of carbon monoxide, or whether it is the arrangement of the cooker above it that is to blame. To decide this and related questions we made use of a galvanized iron box or chamber of one cubic metre capacity in which the stove and vessels were placed for a few minutes at a time. An electric fan kept the air in the chamber thoroughly mixed. A metal rod inserted through the wall of the chamber enabled us to turn off the pressure-release valve on the stove and extinguish the flames before the chamber was opened. The oxygen remaining in the air at the end of each test was determined by means of a Haldane apparatus and the carbon monoxide by means of an iodine pentoxide train.

The Primus, when well pumped up (50 strokes of the pump) and burning freely, produces a remarkably clean, hot flame. When it was tested with no small vessel above it in the cubic metre chamber, we found that it produces virtually no carbon monoxide at all. It produces very little even when—after it has burned for three or four minutes—the oxygen of the air in the chamber has been reduced nearly to 17 per cent, at which point the flame is extinguished.

When a cooking vessel full of cold water was placed upon the frame over the stove at such a height that the upper part of the flame impinged upon the vessel, some carbon monoxide was produced. But the amount was sufficiently small so that the concentration of monoxide in the air in the chamber rose to only 2–3 parts of that gas in 10,000 of air, or 0·02–0·03 per cent, before the oxygen in the air had been reduced nearly to 17 per cent and the flame was nearing extinction. From this we infer that a man could sleep fairly safely in a small airtight room, or hut, with a Primus and one cooking vessel. The flame would be extinguished by the decrease of oxygen before enough carbon monoxide could be produced to endanger him, although he might wake with a headache. He would not be appreciably affected by the decrease of oxygen to 17 per cent. (For comparison it may be recalled that a candle is extinguished at about 17 per cent of oxygen, but a Bunsen burner or 'gas ring' burning town's gas is extinguished only at 12 or 13 per cent of oxygen, which are about the amounts at which a man begins to be markedly affected even during a short exposure.)

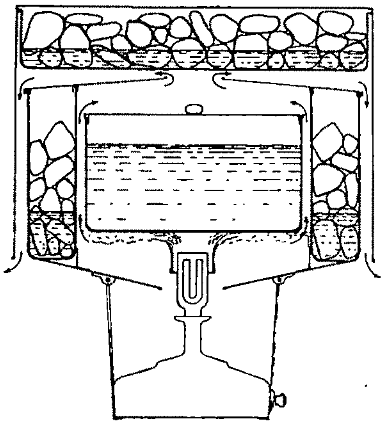

FIG. 1.

PRIMUS STOVE AND NANSEN COOKER AS COMMONLY USED IN POLAR EXPLORATION. HEATING EFFICIENCY UP TO 90 PER CENT. FOR EACH LITRE OF OXYGEN CONSUMED, 20–30 C.C. OF CARBON MONOXIDE MAY BE PRODUCED. IN A SMALL AIRTIGHT CHAMBER ENOUGH CARBON MONOXIDE MAY ACCUMULATE TO ASPHYXIATE A MAN BEFORE THE DECREASE OF THE OXYGEN IN THE AIR TO ABOUT 17 PER CENT EXTINGUISHES THE FLAME OF THE PRIMUS.

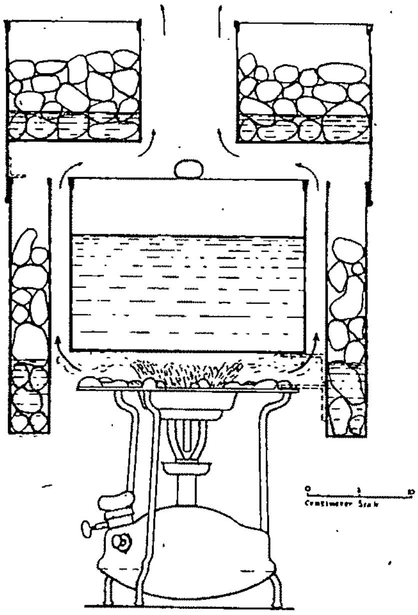

FIG. 2.

PRIMUS AND MODIFIED FORM OF COOKER. HEATING EFFICIENCY ABOUT 70 PER CENT. IF ANY CONSIDERABLE PART OF THE FLAME IMPINGES ON THE CENTRAL POT SMALL AMOUNTS OF CARBON MONOXIDE ARE PRODUCED. IF THE DISTANCE BETWEEN THE BURNER OF THE PRIMUS AND THE BOTTOM OF THE CENTRAL POT IS SUFFICIENT—3–4 CM.—SO THAT THE COMBUSTION IN THE FLAME IS COMPLETE BEFORE THE FLAME IMPINGES ON THE POT, NO CARBON MONOXIDE IS PRODUCED.

When not only the cooking vessel was placed above the Primus, but also the annular vessel for melting ice was placed around it and an additional pan over it, but without the final cover of the cooker, the flame still burned brightly without the slightest smoke or soot; and the concentration of carbon monoxide in the cubic metre chamber did not rise appreciably higher than with only one vessel on the stove.

When, however, in addition to the three vessels, the cover was placed over all, as Nansen, Andrée and others have all used the Primus and cooker, the production of carbon monoxide became so considerable that 8–10 or more parts of that gas in 10,000 of air were developed in the chamber before the flame was extinguished by the decrease of oxygen; and 8–10 or more parts of carbon monoxide in 10,000 of air, if inhaled for more than an hour, can induce a dangerous degree of saturation.

The reasons for the elaborate arrangement of the three vessels and a cover over all, as first adopted by Nansen, were economy and efficiency in the use of fuel. In our hands when well pumped up and burning strongly, the Primus (silent type, large size, capacity 1,100 c.c.) consumes 4–5 grams of kerosene (liquid paraffin) per minute. Taking into account the heat of combustion, the volume of water and the increase of temperature in the contents of the vessels, we have found that when only one vessel is used the efficiency is only 50–60 per cent. When all three vessels are used, but without the cover, the efficiency and economy rise to 70–80 per cent; and with the cover over all, it reaches 80 or even 90 per cent, as Nansen, Shackleton, and others have reported.

With these facts before us, it appears that in Nansen's arrangement (Fig. 1), safety has been too far sacrificed to economy. We suggest, therefore, that the metal cover be omitted, and one of asbestos, or felt, or blanket substituted, with a vent sufficiently wide to offer no obstruction to the escape of the products of combustion; and in addition that some such arrangement of the vessels as that shown in Fig. 2 be adopted: an arrangement suggested to us by Mr. Anthony Fiala.

Even with this arrangement, in which there is a full supply of air and a good draught, some carbon monoxide is produced when the distance between the inner, or cooking, pot and the top of the Primus is so small that some of the flame impinges upon the cold surface of the pot. We find, however, that if this distance is increased so that it is 2 cm. more than the distance now provided between the top of the burner of the Primus and the bottom of the vessel when the vessel is set directly upon the frame of the Primus—or 3–4 cm. in all between burner and pot—no carbon monoxide whatever is produced. With this arrangement, the efficiency of the stove is, however, decreased; and only about 70 per cent of the heat produced by the burning of the fuel is caught in the contents of the three vessels of the cooker.

Whatever arrangement of the cooking and melting vessels may be adopted by future explorers, it would be well, before the expedition starts, to test it by filling the vessels of the cooker with ice and placing it with the lighted Primus in a small room, together with an electric fan to mix the air, and a canary, white mouse, or rat. To be safe, the depletion of oxygen in the chamber should extinguish the flame before the test animal is noticeably affected. With the modified cooker this test may be performed by conducting some of the air from the cooker into a box in which the animal is placed.

NEWS AND VIEWS

Gold Medal of the Royal Astronomical Society

THE Gold Medal of the Royal Astronomical Society has been awarded to Dr. Edwin Hubble, Mount Wilson Observatory, California. Edwin Hubble joined the staff of the Mount Wilson Observatory in 1919. His first work was an investigation of the spectra and luminosity distributions of galactic nebulæ, and he established the now accepted connexion between the light from such nebulæ and the spectra of the stars involved. He proceeded to a general classification of what are now known as extra-galactic nebulæ, and then turned to intensive studies of M31 and M33, which considerably extended the list of novæ observed in them, and he identified Cepheid variables of galactic type as occurring in them. By means of the period-magnitude law for Cepheids he evaluated the distances of these nebulæ, which led in turn to estimates of their dimensions and masses and definitely established not only their extra-galactic nature but also their general similarity to our own galaxy. From this fundamental work followed the recognition of the nebulæ in general as extra-galactic but comparable with our own galaxy in structure. The 'island universe' controversy was thus settled.

Combination of nebular distances with measures of red-shifts (discovered by Slipher but enormously extended by Hubble and Humason) led to the enunciation of the 'velocity-distance proportionality', often called Hubble's Law. This law underlies all modern theoretical cosmology and the concept of the expanding universe. Recent refinements due to Hubble himself have called in question the interpretation of the red-shifts as velocities; but, in whatever form, the apparent increase of velocity at the rate of about 500 km. sec.$^{-1}$ per 10^6 parsecs is a fundamental world-datum. Hubble's more recent researches have been concerned with the distribution of the nebulæ in space and the discovery of their average homogeneity, modified by a tendency to form groups and clusters; with the determination of the mean density of matter in space, another fundamental constant; with space absorption and obscuration in the galactic plane; with the effects of red-shifts on apparent magnitudes; and with the character of the 'local' group of nebulæ. It may fairly be claimed that the modern picture of the universe of extra-galactic nebulæ is largely due to Hubble's researches. He has recently collected them in a book, "The Realm of the Nebulæ", a work of epic quality. His contributions are characterized by the power and originality of his methods, by his observational skill, by the objective character of his deductions and by the general brilliancy of his results.

The Earthquake in Turkey

THE first official estimate of the earthquake losses was given to the Kamutay on January 11 by the Health Minister, who said that there were 23,131 dead and 7,994 injured and that 29,131 houses had been ruined. Further news of the disaster comes from the affected areas as communications are restored. The Susheri district north-east of Erzinjan had been completely cut off for a fortnight except for the dropping of food and medicaments by a squadron of aeroplanes. There were 3,950 dead and 590 injured. It appears that the Malatia Erzinjan railway was not so greatly affected by the earthquake as the Sivas Erzinjan line, though the blizzards and snow affected this line tremendously. According to eye-witness accounts from Rechadiye, there were crevices 400 yards long and several yards wide in different directions. Streams and rivulets have changed their courses. At a place 12 kilometres from Rechadiye a mountain had its shape completely altered, giant precipices being formed and roads being blocked. The Yeshil-Irmak overflowed and further threatened Amasya.

Sailors report that between Kerasun and Shebin-Karihisar an entire mountain has subsided. Photographs from Erzinjan show that movement there took place in all directions, as there appears to have been no predominant direction of fall of the columns and other debris. The town of Erbaa near Tokat has apparently suffered almost as much as Erzinjan, and in many places the bursting of drains due to the earthquake and floods has added new terror. It is reported that typhoid has broken out at Fatsa. After-shocks of decreasing intensity have been felt at intervals in the widely separated areas of Samsun, Amasya, Bursa, Kersund, Yozgad, Inebolu, Bolu, Burdur, Isparta, Karahisar, Erbaa, Akhissar, Odemish, Duzic, Sivas, Tokat, Bergama, Smyrna and Kikili, that is from northern to south-western Anatolia, according to a *Times* report.

The entire body of survivors from Erzinjan, numbering 3,200, have been removed to Alexandretta, Mersin, Adana and other towns of Southern Anatolia, except about 130 injured, who have been placed in hospitals in Istanbul, and the surviving military cadets who have been sent to Konia. It is reported that the Government is discussing a proposal to rebuild Erzinjan on its present site, and temporary wooden cottages are to be erected. Dr. G. Van Dyk states that the first pulse to arrive at De Bilt (Holland) after the earthquake was dilatational, and that possible after-shocks were registered there on December 27 at 22h. 44m. 3s. G.M.T. and on December 28 at 3h. 30m. 45s. and 3h. 35m. 15s. G.M.T. We are indebted to Rev. J. P. Rowland, S.J., of the Stonyhurst College Observatory, for a copy of the seismogram of the principal earthquake. This seems to indicate the possibility of three distinct shocks having occurred within the first minute. They appear to have been of increasing intensity and from very nearly the same epicentre.

Drug Standardization

THE Harrison Memorial Lecture was delivered by Mr. A. D. Powell, chief analyst of Boots Pure Drug Co., Ltd., at the evening meeting of the Pharmaceutical Society on January 9. His subject, "Drug Standardization", was chosen, he said, in token of the work done in that connexion by the late Colonel E. F. Harrison prior to his undertaking the responsibilities of his post as chief of the Defensive Gas Warfare Department during the War of 1914–18. Mr. Powell surveyed the progress of standardization from the time when, as a result of the disclosures of the *Lancet* Analytical Sanitary Commission, the Adulteration Act 1860 was passed, and concluded by outlining his own ideas of the desirable features of a satisfactory drug standard.

Mr. Powell put forward five points: (1) The description and principal requirements of strength should be free from ambiguity, and the descriptive paragraph, if it referred to a drug of definite chemical composition, should not be so restrictive as to insist on a particular method of preparation. (2) The degree of purity in terms of the substance, or of an active principle, should be defined wherever possible, unless, as with many organic chemicals, the melting point gave a sufficient indication of a high degree of purity. (3) The tests for purity should be diagnostic, and preferably capable of application under conditions varying within reasonable limits. (4) The number of tests for purity should cover all the impurities likely to be present in significant proportion, but should be limited by this consideration. (5) Tests to detect traces of unlikely impurities, or a redundance of tests for the same impurity, may weaken rather than strengthen a standard. In general, standardization should be definite and free from ambiguous interpretation; this should not enforce an academically high degree of purity involving artificially high cost of preparation without corresponding advantages in safety and therapeutic activity.

A Pioneer of the Oil Engine

As long as there are oil engines, there will be discussions as to the relative merits of the work of Herbert Akroyd Stuart in Great Britain and of Rudolph Diesel in Germany. Designers of engines to-day utilize the ideas of both, but whereas the name of Diesel has become a household word, that of Stuart is known only among engineers. It was said at the time Stuart died that he "belonged to that rather tragic fraternity of inventors whose achievements have not secured from the world at large the recognition they merited". That his work is fully appreciated in engineering circles was shown by the Diesel Engine Users' Association, which on January 11 held a luncheon at the Connaught Rooms, London, to commemorate the fiftieth anniversary of his most important patents.

After the luncheon, a sketch of Stuart's life and work was given in a paper by Mr. T. Hornbuckle and Mr. A. K. Bruce. Stuart was born in Yorkshire in 1864 and died in West Australia in 1927. He was among the earliest students of the Finsbury Technical College. While engaged at his father's engineering works at Fenny Stratford, Buckinghamshire, he began experimenting with internal combustion engines, and in the years 1886–92 took out nine British patents for improvements. His leading patents were No. 7146 of May 8, 1890, and No. 15994 of October 8, 1890. These were taken out in collaboration with C. R. Binney. In that of May 8, 1890, he claimed the novelty of compression ignition. Diesel's patent was not taken out until February 28, 1892. The manufacture of oil engines according to Stuart's patents was taken up by Messrs. Hornsby and Sons, Ltd., of Grantham, in 1891, and Stuart had little more to do with them. Unfortunately, the engines became known as "Hornsby-Akroyd" engines, and in America even as "Hornsby-Diesels". At his death, Stuart left instructions for his papers to be destroyed, but he bequeathed sums of £500 and £700 respectively to the Institution of Mechanical Engineers and the Institute of Marine Engineers for prizes for papers on oil engines.

British and American Civil Engineers

In September last it had been arranged that representatives of the Institution of Civil Engineers should visit the United States in response to an invitation from the American Society of Civil Engineers, but international unrest in Europe resulted in the cancellation of that visit. Had the visit taken place, it was intended that Mr. W. J. E. Binnie, who was then president of the Institution, should present to the American Society of Civil Engineers a replica of the Myddelton Cup, as a token of the friendly relations which have existed between the two societies. Lord Lothian has now, however, on behalf of the Institution, handed the replica to Colonel D. H. Sawyer, president of the American Society, at a gathering of the members of that Society held in Washington on January 9.

The original Cup was presented to Sir Hugh Myddelton in 1613 by the Worshipful Company of Goldsmiths of London for his services in providing London with a supply of potable water. It remained in the possession of the Myddelton family until 1922, when it was acquired by the Goldsmiths' Company. Lord Lothian has, by completing the ceremony of presentation, cemented the cordial feeling between the two societies and strengthened that part of the bond of international friendship which is based upon the creative genius of the civil engineer in all parts of the world.

Non-Political Work of the League of Nations

A report by the Secretary-General on the work of the League of Nations (July–mid-November, 1939), which has just been issued, is an immediate sequel to the regular report on the work of the League, 1938–39; but is the first of a series which will be published periodically to keep the States Members informed of the progress of the League's work (League of Nations. Report on the Work of the League (Continuation). July–mid-November, 1939. (Official No. A.6(a). 1939.) Pp. 62. (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1939.) 1*s*. 6*d*.). The report shows that with certain exceptions—the European Conference on Rural Life, which was to have met at Geneva in October, for example, had to be postponed *sine die*—the League has been able to carry on, in spite of the War, its essential activities in the non-political fields in which it has been responsible for so much successful and constructive work in recent years. For the development of international co-operation in economic and social affairs, the creation of a Central Committee to direct and supervise the work of the League's Committees dealing with those questions has been recommended and a draft constitution submitted for the approval of the Assembly.

A section in the report on economic and financial questions refers to the meeting of representatives of National Nutrition Committees held at Buenos Aires in October and to measures taken to adapt the publications of the Economic Intelligence Service to the new conditions. Other sections deal with communications and transit, health questions, and traffic in opium and other dangerous drugs. It is interesting to note that maintenance of supervision of this traffic in war-time has been strongly urged by the United States of America, although not a member of the League.

Vital Statistics of a Primitive People

A study of the vital statistics of the lowland Sĕnoi (Sakai) of Perak, Malay Peninsula, by H. D. Noone (*J. Fed. Malay States Mus.*, 15, 4; 1939) is of interest in its bearing on the effect of the inter-racial and cultural contacts of a primitive people on their chances of survival. A generation ago it was regarded as a matter of time only before the then dwindling pagan tribes of the Malay Peninsula would disappear. The observations which Mr. Noone now records, however, suggest that in the group under notice recuperative forces are at work, which enable them at least to hold their own against the effects of Malayan contacts and the adoption by some of their number of the tenets of the Mahommedan faith. In the course of an economic and demographic survey in 1936, Mr. Noone found that in fourteen groups with a population estimated at 1,600 the number of children born to the average lowland Sĕnoi married woman is 4·15, the model family also being four, but with a tendency to increase. The size of the family which occurs so many times as to contribute potentially more to a future generation than any other is five. With this figure as a characteristic, there is ground for hope for the future.

Fertility, reckoned on the basis of the number of children who grow to maturity and become effective in adding offspring to the group, is assessed on the average survival figure of 3·003, the largest number of deaths before maturity taking place under the age of six years. The sex ratio is 100 females to 107·38 males born; and this is practically unchanged at maturity at 100 and 107·54 respectively. These figures, taken in conjunction with other data recorded by Mr. Noone, point to the conclusion that while groups in which contacts have been recent appear to enter upon a stage during which the population suffers a disturbance of its reproduction rate, other groups have passed through this stage and have adjusted themselves well enough to be at least as viable as their more primitive and remoter hill cousins.

Disease and Race

A CASE which is of considerable interest in its bearing upon the racial incidence and distribution of disease is reported from Egypt by S. Azmy Pasha and A. F. Zanaty of Cairo (*Lancet*, 237, December 30, 1939). The patient in question, a man, thirty-five years of age, who had lived in Cairo for twelve years, but previously to that in the country, was admitted to hospital with anæmia in August 1938 and after discharge was re-admitted in a relapse in 1939. After a fortnight's treatment without improvement, a bone marrow puncture not only excluded an aleukæmic leucosis as well as a plastic anæmia, but also showed megaloblasts typical of Addisonian anæmia. Addisonian anæmia, the authors point out, has a distinct racial incidence. It is generally regarded as a disease of Nordic races and as less common among southern races. In America also a higher incidence has been recorded among immigrants from northern Europe (Anglo-Saxon) than among those of Latin extraction. It is also regarded as further supporting this view of racial susceptibility that the Finns, out of all races, are more liable to develop the disease when infested with *Diphyllobothrium fatum*—a parasite which produces a blood-picture indistinguishable from that of genuine Addisonian anæmia. The disease rarely occurs in Asiatics and is unknown in the tropics. In Egyptians it is extremely rare. The authors, after examining hundreds of anæmias, have found only this case now recorded, while another authority has encountered two cases only since 1935.

Demography of Madagascar

IN his inaugural thesis (Thèse de Paris, No. 657; 1939) Dr. Félix Randriamanana states that a study of the population of Madagascar since the beginning of the century shows an annual rise, which was very pronounced during the first twelve years but underwent a decline during each of the subsequent twelve years. In 1936 the population was 3,777,951 as compared with 2,244,876 in 1900. In 1904 and 1908 various devastating epidemics, especially smallpox, measles, malaria and influenza, had a considerable effect upon the population. The annual birth-rate has increased from 64,847 in 1906 to 88,351 in 1936; but the increase is probably more apparent than real owing to the notification of births being carried out more completely then previously.

During 1933–36 the death-rate was 20·7 per 1,000, as compared with 28·5 in Réunion (1933–35), 24 in Egypt (1930–34), 22 in Cochin-China (1931–35) and 15·7 in France (1931–35). During the first year of life the mortality in 1934–36 was 177 per 1,000 births as compared with 83 in France (1930–34) and 206 in Japan (1934). The maternal mortality in childbirth showed a rate of 100 per 1,000 births, this high rate being due to disease and the poor constitution of the mothers. The most prevalent epidemic diseases in Madagascar are plague and malaria at the beginning of summer (December), followed in April by influenza, measles, whooping cough and dysenteries. In June and July pulmonary diseases, especially pneumonia, predominate, followed by influenza, while in September and October more or less severe outbreaks of alimentary diseases are prevalent.

Animal Organisers

Current Science is to be congratulated on presenting to Indian readers a comprehensive résumé of research on organisers ("Organisers in Animal Development", Supp. *Curr. Sci.*, August 1939, Bangalore). There are eight articles contributed by the distinguished investigators, O. Mangold, E. Rotmann, J. Holtfreter, P. Weiss, W. Luther, C. H. Waddington, S. Hörstadius and C. M. Child. Four of the articles are in German, the remainder in English. There are numerous illustrations. The subjects discussed range from the general work of organisers during development and the special factors influencing their activities, to collateral fields of research such as the study of regeneration of lost parts and physiological gradients. A certain amount of repetition and overlapping is inevitable in a series such as this, and it would have been helpful if a summary of the articles could have been provided.

The story of the experimental work undertaken by Spemann and his collaborators at Freiburg im Breisgau on blastoporic organisation centres in the amphibian egg is well known in Great Britain. The old 'epigenesis' versus 'preformation' controversy was thereby revived in a new form. Yet where has it led us? To a slightly better understanding of the laws governing development, but also to obstacles which defy further progress in the present state of our knowledge. For the moment, zoologists have exhausted the subject and await the arrival of a new idea. Some even deny the validity of the organiser theory, and it is possible that much of the work that has been done may be relegated historically to one of those attractive side avenues in science which forms a pleasant rendezvous for a while but is destined to be neglected later because it leads nowhere.

Teaching of Statistics

IN a paper read to the Royal Statistical Society on June 20, 1939, and printed, with the ensuing discussion, in its *Journal* (**102**, 532; 1939), Dr. John Wishart pointed out, among other things necessary for the progress of the subject, the urgent need for a standard treatise on its mathematical side. There are many text-books on practical statistical methods, usually restricted to one particular field of application, such as economics, business statistics, psychology, or biology and medicine, in which the reader has to accept the statements without proof. If a mathematical student asks where these proofs may be found, he may be told "You must look up the original papers, which you will not be able to understand". It is urgently necessary that a text-book should be produced to end this unsatisfactory state of affairs.

Dr. Wishart discussed in some detail what such a text-book should contain, and feared that it was beyond the powers of any one man to produce; he favoured a co-operative venture. However, many will differ from Dr. Wishart on this point, and prefer the incompleteness which may be found in the work of a single writer to the lack of unity characteristic of a book produced by a committee. In the interests of science it is desirable that we should not have to wait indefinitely until the ideal treatise can be produced. Let someone have the courage to make the attempt now; there is no one better qualified for the task than Dr. Wishart himself.

Meteorology in Southern Rhodesia

THE meteorological report of the Department of Agriculture, Southern Rhodesia, for the year ended June 30, 1938, covers the period during which the Northern Rhodesia Weather Service was taken over from the British East Africa Meteorological Service by arrangement with the Governments concerned. After the transfer, the establishment of a new air route in Northern Rhodesia was announced by the Government of that country to replace the existing route via Broken Hill and Mpika, and this led to the setting up of a first-order meteorological station at Lusaka, while arrangements were made to open another at Kasama later. Civil aviation developed to twice its initial volume during the period in Southern Rhodesia, and the Service found it difficult to meet the increased demands for weather reports. The formula used for the previous ten years for forecasting the seasonal rainfall gave a prediction of abundant rainfall for 1938–39, with a result that could not of course be indicated at the time of completion of this report. The only previous comparable prediction of abundant rainfall was for 1934–35, and was the most conspicuous of only three failures out of the previous nine predictions to forecast whether the rainfall would be above or below the average. On one of these three occasions the predicted and actual departures were so small that it can reasonably be regarded as a successful forecast, making the successes nearly eighty per cent, which is a very satisfactory result. It is stated that the predictions have proved of value, as may easily be credited in view of this high percentage. The report, as usual, includes extensive meteorological tables for a large number of stations for the year, among them those giving hourly values of several items for Salisbury Observatory.

Mistletoe, Magic and Medicine

THE October issue of the *Bulletin of the History of Medicine* contains an excellent survey by Dr. Leo Kanner, of Baltimore, of the history of mistletoe from the earliest times until the present day. The magic virtues formerly attributed to it were as follows: it was regarded as a promoter of grain and fruit harvests; a fattener of live-stocks; an incentive to milk production; a safeguard against ghosts and witches, nightmares and conflagrations; a bringer of luck to farmers, home owners, hunters, warriors, wrestlers and travellers; an agent which forces spirits to reveal their secrets; a discoverer of buried treasures, and a feeder of the mystic mandrake. It was also characteristic of its magic powers that mistletoe was regarded as a panacea, as it was used for the prevention and cure of plague, leprosy, fevers, syphilis, consumption, hæmorrhages, diseases of the heart and lungs, intestinal disorders, poor appetite, skin affections, nervous troubles and, most of all, epilepsy.

On the other hand, mistletoe was sometimes regarded as a baleful plant and was supposed to possess poisonous properties for which numerous remedies were prescribed by Galen and others. In the first half of the nineteenth century all the therapeutic properties of the mistletoe had become discredited, and it was not until 1906 that it became permanently established as a useful drug for the treatment of hypertension and later as a diuretic and styptic.

Tests of a 4,000 kw. Gas-Turbine Set

PROF. A. STODOLA, in *Engineering* of January 5, gives a description and test results of a 4,000 kw. combustion-turbine generating set, recently constructed by Messrs. Brown, Boveri and Co., Ltd., of Baden, Switzerland, for the city of Neuchâtel. The set was built for installing in a bomb-proof chamber for use in emergencies, and consists of an axial-type air-compressor, a combustion chamber, a gas-turbine exhausting direct to the atmosphere, and an electric generator. "The present-day possibilities of realising a successful gas-turbine, resulting from the improvement of the compressor efficiency on the one hand, and the availability of heat resisting materials on the other hand, would have appeared unthinkable but a short time ago."

When the set is working, with the temperature of the atmosphere about 77° F., air from the compressor is discharged at a pressure of about 60 lb. per sq. in. and a temperature of nearly 400° F. to the combustion chamber. The fuel is gas oil. Only a part of the air is used for combustion, the remainder being used to bring down the temperature of the burnt gases to about 1,000° F., at which temperature they enter the turbine. After doing work in the turbine, the gas is exhausted to the atmosphere at a temperature of about 500° F. The set is rated at 4,000 kw., and revolves at 3,000 r.p.m., producing three-phase current at 50 cycles. The thermal efficiency is 17·38 per cent. The gas turbine, says Prof. Stodola, has many promising possibilities which merit the attention of prime-mover designers and of leaders of industry.

Swiss Watch-making Industry

IN *Swiss Technics*, published by the Swiss Office for the Development of Trade, in Zurich and Lausanne, during November–December 1939, it is stated that although less trade was carried out during the first few months of the year than during the corresponding months of 1938 there was decided improvement in the summer, so that exports to most foreign countries very nearly reached the 1938 figures. This progress would certainly have been maintained had it not been for the War. It would be absurd to give way to despondency with regard to the future of the Swiss watch-making trade. There are two good reasons for looking forward hopefully. The first is the great improvements made by the industry in perfecting watches during the last ten years. The improvements have been continuous.

The 1939 steel watch is proof against fall, shock and damp. It is antimagnetic and does not oxidize. It unites a number of advantages and improvements not found in the best watches made before the War of 1914–18. The manufacturers are not afraid of losing their customers. As an example they give Great Britain, where the demand is increasing owing to the greater need for punctuality. The second reason lies in the organization of the Swiss watch-making industry. The watches are made of good materials and with great technical skill. Quite poor people will always find good watches at a price suited to their purses. Competition which the Swiss might justly have feared has now disappeared. They are therefore prepared to provide the world with the three types of watches produced by a trade that is built up on sound principles: chronometers and precision instruments, suitable for observatories, beautiful high grade watches, and cheaper watches which nevertheless keep good time. It is thus that the Swiss industry faces the great crisis.

Earth Tremors in Belgium

ON January 7 two earthquake tremors were distinctly felt in the district immediately to the east of Mons, one at about 4.30 p.m. and the other at about 8.30 p.m. These were recorded at the Uccle Observatory at 4.29 p.m. and 8.32 p.m. respectively and the epicentre appears to have been near latitude 50° 26′ N., longitude 4° 0′ E. No damage or casualties are reported. It will be remembered that a much stronger earthquake did damage to property and caused injury to ten people in Belgium on June 11, 1938 (NATURE, **144**, 950; 1939). On that occasion the epicentre was determined by the chief of the Belgian Seismological Service, Dr. O. Somville, to have been between Audenarde and Renaix, latitude 50° 47′ N., longitude 3° 35′ E. The 1940 epicentre thus appears to have been a little to the south and east of the 1938 epicentre, though any connexion between them is doubtful. The 1938 earthquake had a depth of focus of 45 km. though the 1940 one may have been superficial.

Development of Moscow

A BOOKLET recently issued in Moscow entitled "Moscow in Figures" (London: Russia To-day Press Service) shows the development of the Soviet capital in recent years. According to the figures given, during the last thirteen years the population of Moscow has more than doubled, at present numbering 4,137,000. Moscow is now the third largest city in the world. The number of workers and employees in the factories and institutions of Moscow in 1939 reached 2,300,000, as against 600,000 in 1913. In 1938 there were 117,200 births in Moscow. The city has 175 scientific research institutions in which 9,000 scientific workers are engaged. The higher educational institutions of Moscow have 95,000 students. During the last four years 350 new schools have been built. The number of pupils at present attending the Moscow schools is 608,300.

Hygiene in South China

THE November issue of the *Bulletin de l'Office d'Hygiène Publique* contains an account by Inspector-General Dr. A. Lasnet, the delegate of Algeria, of a sanitary mission sent by the Health Section of the League of Nations to South China in December 1937, six months after the onset of the war between China and Japan. The work of the mission consisted in (1) a campaign against infectious diseases, especially smallpox during the cold season, cholera during the hot season and malaria in the spring and summer; (2) wholesale destruction of insanitary houses, construction of wide sunny streets, proper disposal of excreta, and protection of the water supply; (3) education of the population in hygiene.

Detection of Toxic Gases

LEAFLETS 8 and 9 of "Methods for the Detection of Toxic Gases in Industry", published by the Department of Scientific and Industrial Research

(H.M. Stationery Office, 2*s*. 6*d*. each net) deal with phosgene and arsine, respectively. The methods used are colorimetric, the reagents being diphenylamine and *p*-dimethylaminobenzaldehyde in the case of phosgene, and mercuric chloride in the case of arsine. Full directions for performing the tests are given.

Colonial Service Appointments

THE following appointments and promotions in the Colonial Service have recently been made: M. Lunan and C. Mansfield, agricultural officers, Tanganyika Territory; A. H. Milne, veterinary officer, Nyasaland; H. W. C. Newlands, veterinary officer, Tanganyika Territory; R. H. Owen, veterinary officer, Gold Coast; C. D. V. Georgi, senior chemist, Research Branch, chief research officer, Agricultural Department, Malaya; R. R. Glanville, senior agricultural officer, Sierre Leone, principal agricultural officer, Nigeria; W. G. Leckie, senior agricultural officer, Kenya, deputy director of agriculture, Basutoland; F. A. Squire, entomologist, Windward and Leeward Islands, entomologist, Sierra Leone; C. A. Thorold, plant pathologist, Kenya, plant pathologist, Department of Agriculture, Trinidad; R. G. M. Willan, assistant conservator of forests, Nyasaland, assistant conservator of forests, Cyprus.

Prize Awards of the Paris Academy of Sciences

THE annual public meeting of the Paris Academy of Sciences was held in December, and the customary long list of prize and medal awards for 1939 has been published. Lack of space precludes publication of the complete list of awards, most of which naturally go to French workers, but the names of the following investigators outside France who received prizes may be put on record: Prof. Nicolas Coculesco, honorary director of the Observatory and honorary professor of the Faculty of Science of the University of Bucharest, the G. de Pontécoulant Prize for his studies of celestial mechanics, especially on the development of the perturbing function; Prof. Lucien Dautrebande, of the University of Liège, a Montyon (Unhealthy Trades) Prize of 2,500 francs for his researches during the past twenty years on the toxicology of the vapours of different solvents used in industry; Prof. Pierre Coulouma, of Lille, and director of the Institute of Anatomy of Fribourg, and Léon Devos, of the Faculty of Medicine of Lille, a Montyon Prize of 2,500 francs for their work entitled "Les zones pulmonaires. Anatomie et radiologie chez l'Homme. La lobation et la zonation des poumons. Études d'anatomie comparée chez l'Homme et les Mammifères".

Food Rationing: Special Diets

AT the request of the Ministry of Food, the Ministry of Health, and the Department of Health for Scotland, the Medical Research Council has appointed an expert committee "to advise from time to time on the question whether it is necessary on medical grounds to modify or supplement rations in the case of invalids and other persons on special diets". The following have accepted the Council's invitation to serve on the committee: Sir Edward Mellanby (chairman), secretary of the Medical Research Council; Prof. L. S. P. Davidson, professor of medicine in the University of Edinburgh; the Right Hon. Lord Dawson of Penn; Prof. F. R. Fraser, professor of medicine in the British Postgraduate Medical School, London; Prof. H. P. Himsworth, professor of medicine in University College Hospital Medical School, London; Dr. R. D. Lawrence, King's College Hospital Medical School, London; Dr. R. A. McCance, reader in medicine in the University of Cambridge; Dr. J. C. Spence, Victoria Infirmary, and clinical teacher in medicine in King's College, Newcastle-on-Tyne. The committee will hold its first meeting at once, when the question of diabetic diets will be particularly considered.

Announcements

DR. C. H. DESCH retired from the post of superintendent of the Department of Metallurgy and Metallurgical Chemistry, National Physical Laboratory, on December 31 last, having attained the normal age limit. Dr. Desch will be succeeded by Dr. C. Sykes, of the Metropolitan-Vickers Research Laboratories, who will take up his duties at Teddington on March 1.

THE annual general meeting of the London and Home Counties Branch of the Institute of Physics will be held on January 25, in the lecture theatre of the Royal Institution, London, W.1. At the conclusion of the business, a lecture will be given by Dr. H. Spencer Jones, Astronomer Royal, entitled: "The Measurement of Time".

THE next meeting of the Plastics Group of the Society of Chemical Industry will take the form of a joint symposium with the Faraday Society at Caxton Hall, Caxton Street, Victoria Street, S.W.1, on January 26, at 6.30 p.m. The symposium will be entitled: "Molecular Size and Structure and their Influence on the Properties of Plastics". Further information can be obtained from the Hon. Secretary of the Plastics Group, Society of Chemical Industry, Clifton House, Euston Road, London, N.W.1.

THE Hotel Dieu of Quebec, the oldest hospital in Canada, and with the possible exception of one in Mexico, the oldest hospital in North America, has recently celebrated the tercentenary of its foundation.

THE centenary of the foundation of the Belgian Royal Academy of Medicine will be celebrated on September 19, 1941.

THE New York office of the United States Public Health Services is sponsoring the formation of a Society for the Study of Syphilis for all physicians in the city who are interested in the diagnosis and treatment of the disease.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 111. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Evidence for Transformation of Mesotrons into Electrons

ONE of the outstanding questions regarding the mesotron is that of its ultimate fate. Certain properties of this particle are remarkably like those of the hypothetical particle assumed by Yukawa in his theory of nuclear forces and β-disintegration, and this has led to the view that the two may be identical. Within a rather large experimental error they have the same mass, and both are unstable in the free state, having an average life of the order of 10^{-6} seconds. The disappearance of the particle of Yukawa's theory at the end of its life takes place through its transformation into an electron and a neutrino, and it is regarding this that hitherto there has been no evidence of a parallel between it and the mesotron of cosmic rays. In fact, existing experimental evidence has rather gone to show that mesotrons suffer at the end of their life some other fate than befalls the Yukawa particle.

With the object of obtaining information on this crucial point we constructed a large cloud-chamber (24 in. diameter, 20 in. deep) which, with its large sensitive period and volume, might catch a cosmic ray mesotron coming to the end of its range in the gas of the chamber. A recent photograph taken with this shows a mesotron track terminating in the gas as desired. From its end there emerges a fast electron track, the kinetic energy of which is very much greater than the kinetic energy of the mesotron, but is comparable with its mass energy. This indicates that the mesotron transforms into an electron, in which case the remarkable parallel between the mesotron and the Yukawa particle is taken one stage further. In terms of Yukawa's theory, the phenomenon observed may be described as a disintegration of the mesotron with the emission of an electron, thus constituting the most elementary form of β-disintegration.

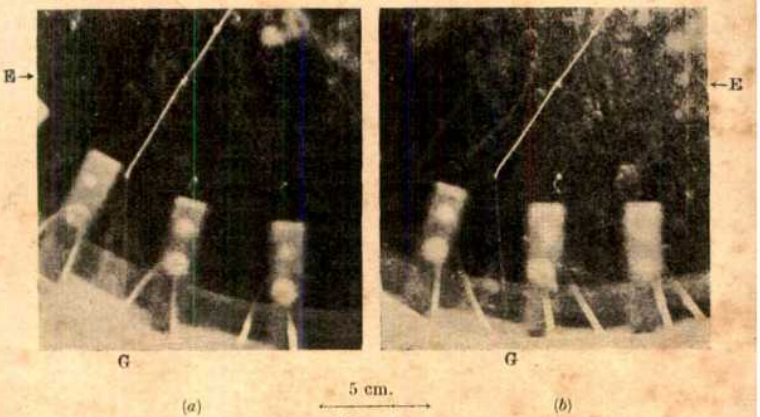

Fig. 2.

a AND *b* ARE ARRANGED FOR STEREOSCOPIC OBSERVATION WITH THE NAKED EYE, WHEN USUALLY THE LEFT EYE SEES THE RIGHT-HAND PICTURE.

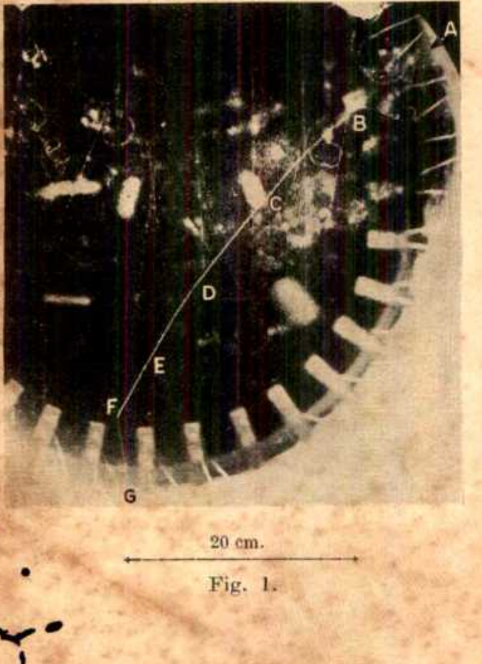

Fig. 1.

Fig. 1 is a reproduction of one of the photographs of the stereoscopic pair. The dense track *AF* is that of the mesotron, and the faint track *FG* leaving its end, near the bottom of the chamber, is that of the fast electron. It will be noticed that the latter is comparable in density with the tracks of other fast particles which happened to traverse the chamber in the same region. Fig. 2 is a larger reproduction of the stereoscopic pair, showing only the end portion of the mesotron track and the emergent electron (2*a* is not in as good focus as 2*b*). Fig. 3 is a heavily exposed reproduction of the last few millimetres of the mesotron track to bring out its shape though the electron track is thereby nearly lost, and Fig. 4 is an enlargement of the δ-track at *E* to show more clearly its initial direction. The tracks in the present reproductions are much less distinct than in the original negatives and photographic prints, and this particularly applies to the fast tracks (including

FG) and the short δ-tracks, of which there are at least six obvious ones to be seen between *C* and *F* on the original negative.

That the dense track is that of a mesotron follows from its range and curvature, and from the δ-tracks. An accurate estimate of the mass from the curvature is not possible because the scattering which the particle suffers interferes appreciably with the curvature due to the magnetic field. The straightness of *FG* and of neighbouring fast tracks shows that there was no appreciable distortion from air motion. The radius of curvature, ρ, at *B*, measured over *AC* (~ 20 cm.), is 70 cm., giving $H\rho = 1180 \times 70 = 8\cdot3 \times 10^4$. The range beyond *B* is 33 cm. in the chamber, corresponding to 41 cm. of normal air. These data give a mass, μ, of $(250 \pm 70)\ m$, where m represents electronic mass. This is of the same order as previous estimates of the mass of the mesotron, and is sufficiently far removed from the mass of the proton (1840 m) to establish the particle as a mesotron. The number and range of the δ-tracks also indicate mesotronic mass, and rule out a proton. In particular the long δ-track at *E*, which in the reproduction in Fig. 3 is seen to be directed nearly forward, has a path-range, R', equal to $0\cdot06 \pm 0\cdot03$ times the remaining range, R, of the heavy particle. This is roughly the range that would be expected for a secondary electron knocked nearly forward by a mesotron with the observed remaining range. It is, however, at least five times greater than the range of the longest δ-track that could be produced by a proton. The latter is approximately $(2^{3\cdot4}/1840)R = 0\cdot006R$. Regarding the 'scattering' of the track, while it is more pronounced than the *average* effect expected for a mesotron, it is more compatible with the latter than with a proton or any other known particle. The natural 'curvature' of cloud-tracks due to multiple and single scattering is discussed by one of us in a paper now in the press (*Physical Review*). It is there shown that towards the end of its range—last 5 cm. or so—the natural curvature of a mesotron track may well exceed its magnetic curvature in a field of 1,200 gauss. (The 'kink' at *D* contributes little to the average curvature and is possibly more a thinning of the track on one side than a true deflection. The 'single' scattering at *C* appreciably reduces the overall curvature.) The bending of the track in the last 5 mm. or so (Fig. 3) is of interest. It indicates that the mesotron has come to the end of its range, thus discounting the possibility that the photograph represents the production of a mesotron and an electron by a neutral particle. Against this supposition are also the facts that the long δ-track at *E* is initially directed forward, and that the δ-tracks are more numerous in the lower half of the track. Both indicate motion of the mesotron towards *F*.

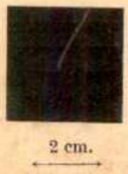

Fig. 3

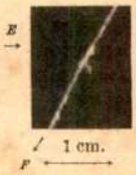

Fig. 4

The curvature of the electron track, *FG*, is very small. Actually there is detectable (Fig. 2*b*), a small curvature in a direction indicating a positive charge, which is also the direction of the curvature of the mesotron. The photograph thus represents a positive mesotron transforming into a positive electron. So far as it can be estimated, the radius of curvature of *FG* is 200 cm. ± 50 per cent, which in the field of 1180 gauss (neglecting any distortion due to air-motion) indicates an energy of 70 Mev. ± 50 per cent. Taking $\mu = 200\ m$, and assuming that a neutrino takes half the energy, the energy of the electron would be 100 $mc^2 = 50$ Mev.

The large energy of the electron shows, quite apart from Yukawa's theory, that mass has been annihilated—for the mesotron, even if we suppose it has disintegrated before 'stopping', has certainly less than 4 Mev. of kinetic energy. Actually, the large bending of the end of the mesotron track indicates (as already pointed out) that *E* is the normal end of its range, where it has reached too low a velocity to ionize further. In this connexion it is of interest that an upper limit to the lifetime, τ, of this mesotron, since its entry into the chamber, can be set from the fact that the electron track starts from a point certainly not more than 0·4 mm. from the end of the mesotron track. Assuming the mesotron, after it ceases to ionize, to diffuse with gas-kinetic free path (10^{-5} cm.) and thermal velocity (10^6 cm./sec.) this gives an upper limit to τ of $(0\cdot04^2/10^{-5} \times 10^6) \sim 2 \times 10^{-4}$ seconds. Actually it is likely that a mesotron, when it stops ionizing, has a velocity of at least 10^7 cm./sec., and a free path considerably greater than gas-kinetic values, so that τ must be much less than the above limit. The average value of τ deduced from the anomalous absorption of cosmic ray mesotrons is of the order of 10^{-6} seconds.

Large Cosmic Ray Showers and Mesons

IT has been pointed out recently by Bhabha, Carmichael and Chou[1] that a meson may produce a large cosmic ray shower by knocking on an atomic electron in a close collision; this electron then produces a shower by the ordinary cascade process. Previously, Bhabha[2] had come to the conclusion that large knock-on showers are comparatively unimportant; but he had based his argument on the assumption that the scattering of mesons by electrons could be described by the Dirac relativistic theory. However, Massey and Corben[3] have shown that the effect of the spin of the meson is greatly to increase the scattering for high energies of the incident meson and the knocked-on electron. Using Massey and Corben's formula, Bhabha, Carmichael and Chou have shown that the experimental results of Carmichael and Chou[4] can be reasonably well explained, whereas the previous theory predicted too few large showers.

There is, however, another process which has to be considered. In passing a nucleus, a meson may emit a very hard γ-ray, and this γ-ray will start a cascade shower. Since γ-rays and electrons are about equally efficient in producing showers, it is only necessary to consider the relative magnitude of the cross-sections for knocking-on an electron and producing a γ-ray of the same energy, and it appears from calculations which we have recently carried out that at sufficiently high energies the production of a γ-ray is the more probable process.

The direct calculation of the radiation loss by mesons is distinctly complicated. We have, therefore, used the method of impact parameters employed by v. Weizsäcker and by Williams for discussing the corresponding electron problem. This method requires a knowledge of the scattering cross-section for light quanta by mesons which are initially at rest. We have calculated this, using Kemmer's new matrix formulation of the meson equations[5], which is particularly well adapted to the treatment of problems not involving the nuclear interaction. We have then used this formula, which is too complicated to be quoted here, to obtain the radiation loss in the extreme relativistic case. We find that the differential cross-section for the process in which a meson of energy E collides with a heavy nucleus of atomic number Z and emits a γ-ray the energy of which lies in the range εE, $(\varepsilon + d\varepsilon)E$, is

$$\frac{1}{137}\,\frac{Z^2}{12}\left(\frac{e^2}{mc^2}\right)^2\frac{E}{mc^2}\,(2-2\varepsilon+7\varepsilon^2)d\varepsilon, \qquad (1)$$

where m is the mass of the meson. (This formula does not apply to very small values of ε.)

The corresponding cross-section for the knock-on process in which the meson gives up a fraction ε of its energy to one of the Z atomic electrons is

$$\frac{\pi}{3}Z\left(\frac{e^2}{mc^2}\right)^2(2-2\varepsilon+\varepsilon^2)\frac{d\varepsilon}{\varepsilon}. \qquad (2)$$

Hence, for energies greater than about 300 mc^2/Z, that is, about 4×10^9 ev. for air and about 4×10^8 ev. for lead, the emission of a γ-ray is the more probable process. It is, therefore, clear that the calculations of Bhabha, Carmichael and Chou must be modified; the revised theory will give an even greater number of large showers.

It is also of interest to compare (1) with the corresponding formula for electrons, which according to v. Weizsäcker is, with sufficient accuracy,

$$\frac{4Z^2}{137}\left(\frac{e^2}{m_ec^2}\right)^2\log\frac{137}{Z^{\frac{1}{3}}}\left[\frac{4}{3}(1-\varepsilon)+\varepsilon^2\right]\frac{d\varepsilon}{\varepsilon}, \qquad (3)$$

where m_e is the electronic mass. We see that in spite of the much larger mass of the meson, the cross-section for the emission of a very energetic γ-ray (for which $\varepsilon \sim 1$) is greater for mesons than for electrons, provided that the energy is greater than about $3 \times 10^{13} \log (137Z^{-\frac{1}{3}})$ e.v. Similarly, we can conclude that a γ-ray with energy greater than about 10^{14} ev. is more likely to produce a meson pair than an electron pair, provided of course that the electron theory and the meson theory both remain valid in this region. As a consequence of this we may expect to find cascade showers consisting mainly of mesons and γ-rays high up in the atmosphere. As the energies of the individual particles diminish, the number of mesons will decrease, since electrons will be created instead of mesons when the energies of the γ-rays fall appreciably below 10^{14} ev.

Full details of the calculations will be published when circumstances permit.

Series in Nuclear Energy-Levels

P. G. Kruger, F. W. Stallmann and W. E. Shoupp[1], investigating the γ-spectrum and the spectrum of the emitted neutrons of the reaction ${}^{9}_{4}\mathrm{Be} + {}^{2}_{1}\mathrm{D} \rightarrow {}^{11}_{5}\mathrm{B} \rightarrow {}^{10}_{5}\mathrm{B}^* + {}^{1}_{0}n \rightarrow {}^{10}_{5}\mathrm{B}$, have found a system of excitation energy-levels of the nucleus ${}^{10}_{5}\mathrm{B}$ with the values 0·26; 0·50; 0·61; 1·44; 1·93; 2·92; 3·64 and 4·73 Mev., which they interpret as ${}^3D_{1,2,3}\ {}^1S\,{}^1D\,{}^3D\,{}^1D\,{}^3F$ levels.

It is worth remarking that the second, fourth, sixth and eighth terms can be represented by the formula $E_K = 0{\cdot}239\ K(K + 1)$ Mev., with $K = 1;\ 2;\ 3;\ 4$; that is, 0·478; 1·434; 2·868 and 4·780 Mev. (by the method of least squares), the deviation of the experimental data being much smaller than the error of 5 per cent admitted by the authors. The formula above corresponds to the law of terms of the rigid rotator in quantum mechanics $E_K = K(K + 1)\hbar^2/2J$, where K is the angular quantum number and J is the moment of inertia.

Also, the ratio of the third and the seventh term being 1 : 6 fits surprisingly well into the scheme above with $K = 1$ and $K = 3$. In consequence, we should expect a further term with $K = 2$; and there is such a term (the fifth) at 1·93. The method of least squares leads to 1·84 Mev., just within the limit of the error admitted by the authors, and to $E_K = 0{\cdot}307\ K(K + 1)$ Mev., with $K = 1;\ 2;\ 3$. The moments of inertia are then $J_1 = 1{\cdot}45 \times 10^{-48}$ and $J_2 = 1{\cdot}13 \times 10^{-48}$ gm.cm.^{2}. Inserting the mass of ${}^{10}\mathrm{B}$, we can calculate a lower limit of the radius of the rotating nucleus to be $r > 2{\cdot}6 \times 10^{-13}$ cm., which appears a reasonable value. With spherical distribution of the particles ($J = \frac{2}{5}Mr^2$), we get $r_{\mathrm{sph.}} = 4{\cdot}15 \times 10^{-13}$ and $4{\cdot}71 \times 10^{-13}$ cm. respectively. That we find two different moments is due either to isomerism of the nucleus ${}^{10}_{5}\mathrm{B}$ or to a non-spherical symmetry of the nucleus. Thus all terms equal to or greater than 0·48 Mev. of ${}^{10}_{5}\mathrm{B}$ can be represented as terms of the rigid rotator, and the law is confirmed with eigen values 10^{10} times as great as in molecules.

The term law of the rotator can be applied also to other nuclei. For example, in ${}^{26}\mathrm{Mg}$, excitation levels are known[2] at 2·3, 4·0 and 5·0 Mev. With $E_K = 55{\cdot}5\ K(K + 1)$ kv., $K = 6;\ 8;\ 9$; we get 2·33; 4·00 and 5·00 Mev. For the moment of ${}^{26}\mathrm{Mg}$ we find $6{\cdot}25 \times 10^{-48}$ gm.cm.^{2}, $r_{\mathrm{sph.}} = 6{\cdot}06 \times 10^{-13}$ cm.

Even for nuclei as heavy as ${}^{223}\mathrm{Ac}X$, the law of rotation holds and provides a description of the energy levels. Analysing the α-rays of ${}^{227}\mathrm{RaAc}$, S. Rosenblum[3] has found levels at 30; 61; 81; 135; 174; 197; 235; 247; 288; 313; 335; 386 kv. (some other very feeble ones are not yet determined exactly). With the formulæ $E_K = 1{\cdot}496\ K(K + 1)$ kv. and $E_K = 1{\cdot}594\ K(K + 1)$ kv., using least squares, we get corresponding levels at 29·9; 62·8; 83·6; 134·6; 175·3; 197·5; 233·2; 248·7; 290·1; 314·2; 334·7; 382·6 kv. These levels are also in conformity with the experimental data of γ-rays. In particular, we find for the highest term:

382·6 — 334·7; 233·2; 210·4; 62·8; 29·9 kv.
differences 47·9; 149·4; 172·2; 219·8; 352·7 kv.

γ-Rays are measured with
47·9; 149·2; 172·7; 219·4; 353·0 kv.

The moments of ${}^{223}\mathrm{Ac}X$ come out to be $J = 2{\cdot}18 \times 10^{-46}$ and $J = 2{\cdot}32 \times 10^{-46}$ gm.cm.^{2}

respectively; the radii $r_{\text{sph.}} = 1{\cdot}22 \times 10^{-12}$ and $1{\cdot}26 \times 10^{-12}$ cm. respectively.

In accordance with the assumption of equal density, the $\frac{2}{3}$ powers of the mean values of the moments of inertia of the three atomic nuclei described above are proportional to the atomic weight within 1 per cent, namely, 10 : 26 : 223.

A more detailed discussion and the application to other nuclei will be published elsewhere.

Wave-length Effect in the Reaction of Human Skin to X- and Gamma-Radiation

THE quantitative variation with wave-length of the reaction of human skin to X- and γ-radiation is of both clinical and biological importance. Of especial interest is the determination of the ratio of the biologically equivalent doses, appropriately measured in röntgens, of X-radiation of effective wave-length 110–170 X.U. and of γ-radiation of wave-length 10–20 X.U. It is an accepted clinical observation that the dose of X-radiation equivalent in the production of skin erythema to 1 r. unit of γ-radiation is less than unity, and recent work[1] suggests a value of the order 1/1·3. However, in this and most other studies, the depth dose distribution was very different for the two radiations.

During a clinical investigation with another object, I have examined the skin reactions produced by γ-radiation in which the depth dose at 0·5 cm. was 97–108 per cent; this distribution was attained during the treatment of cases of carcinoma of the lip, by means of two-plane moulded applicators. Routine X-ray therapy has made comparison possible and ten of the γ-ray cases were selected together with ten suitable cases receiving X-radiation of approximate effective wave-length 145 X.U. In both groups, the end-point observed was the onset of moist desquamation and the overall time of irradiation was 192 hours. The dosage rates were 0·906–1·26 r./min. for γ-radiation and 28·0–31·5 r./min. for X-radiation; in the former case, the intervals between the exposures were never greater than 12 hours; but in the latter, two 48-hour intervals occurred together with the usual 24-hour intervals. Recent experiments[2,3] show that these differences in dosage rate and time spacing produce an error not greater than 5 per cent in the required ratio. The X-ray apparatus was calibrated using a rice phantom and a Victoreen dosimeter, and the measurements were kindly checked by Dr. D. E. Lea using a free air ionization chamber. The γ-ray intensities were calculated assuming that 1 Imc. hr. = 8·4 r., and the homogeneity of the field at the skin was checked photographically. Clinically similar reactions were observed, among these twenty selected cases, with X-radiation with a mean dose 4,250 r. (minimum 4,200 r., maximum 4,500 r.) and with γ-radiation with a mean dose 5,790 r. (minimum 5,490 r.; maximum 6,500 r.); the reaction did not occur with γ-ray doses 5,200 and 5,350 r. From the results, it is concluded that 0·7–0·8 r. unit of X-radiation of effective wave-length 145 X.U. is equivalent, in the production of moist desquamation of normal human skin, to 1 r. unit of γ-radiation of effective wave-length 15 X.U.

It is important to know whether this result is capable of quantitative explanation in terms of the contribution from photo-electric absorption in the heavier elements present, including the sulphur of the stratum corneum. Tedious but straightforward calculations, including once-scattered radiation, show that the 'physical erythemal effectiveness' W_λ, for radiation of primary wave-length λ, which is defined as proportional to the ratio of the energy absorptions per unit volume in tissue at depth $z \approx 0{\cdot}1$ mm. and in a small air cavity at $z = 0$ half embedded at the surface of a phantom, is given by:

$$W_\lambda = k\frac{(\tau+\sigma_a)_{\text{tissue}}}{(\tau+\sigma_a)_{\text{air}}}e^{-[\mu_c z_c + \mu\ (z-z_c)]}\left\{1+K(\lambda)\right\},$$

where k is an arbitrary constant, τ and σ_a respectively the photo-electric and scattering absorption coefficients at λ, μ_c the absorption coefficient and z_c the thickness of the stratum corneum and μ the absorption coefficient of the subjacent tissues. $K(\lambda)$ is a slowly varying function of λ and is ≤ 3 per cent for λ = 145 X.U. This equation has been tested by calculating the value of $\frac{(\tau+\sigma_a)_{\text{tissue}}}{(\tau+\sigma_a)_{\text{air}}}$ for a large number of possible (and improbable!) tissue and nuclear compositions[4,5] using Sauter's formula to obtain τ.[6] From the results, the conclusion must be reached that these physical considerations cannot possibly lead to a value of the ratio less than 0·9, which is significantly greater than that observed.

In seeking an explanation in terms of a chemical process, the participation of excited molecules[7] appears to be supported by the similarity of the photo-chemical changes produced in certain organic compounds by ultra-violet and X- and γ-radiations[8]. Further, the theoretical possibility of a small wave-length effect, but in the opposite direction to that observed, is introduced by the work of Bethe[9], who showed that during the passage of fast electrons through atomic hydrogen the ratio of the probabilities of excitation to ionization processes increased slowly with the energy of the electron. The similarity of the values of the ionization and excitation potentials[10] suggests that the effect may be of the same order for water as for hydrogen. Calculations on this basis (including secondary processes) show that in water the ratio of the number of excitation to ionization processes for radiation of wave-length 12·1 X.U. is $\leq 1{\cdot}05$ times the value for the wave-length 121 X.U.; hence this effect is not likely to be of importance.

These considerations suggest that the observed response of human skin to X- and γ-radiations cannot be attributed quantitatively to its exceptional histological and chemical structure alone, as appears to be the case for the wave-length effect with ultra-violet radiation[11], and it is worthy of note that similar values of the ratio discussed are suggested by recent work on other living cells, assuming that 1 Imc. hr. = 8·4 r.; for example, 0·65 for Drosophila eggs[12], 0·73 for Drosophila pupæ[13]. Comparison of the ratio for normal and neoplastic tissues would be of great radio-therapeutic interest.

I wish to express my grateful acknowledgment to the Medical Research Council for financial assistance.

Cozymase in Adrenalectomized Rats

DURING recent years, Verzár and his co-workers have tried to demonstrate that the adrenal cortical hormone plays an important part in the phosphorylations of the body. They have, among other facts supporting this hypothesis, shown that lactoflavine has no B_2-effect in adrenalectomized rats. In these, however, the full vitamin effect is obtained by lactoflavine-phosphate[1]. They have further shown that in adrenalectomized rats the liver contains abnormally small amounts of fixed lactoflavine[2].

In view of these findings, we have thought it of interest to investigate whether the metabolism of cozymase, another prosthetic group carrying the PO_4 group at quite a different position from that of lactoflavine, is influenced by adrenalectomy.

White rats weighing 100–250 gm. were used. They were kept on a diet of white bread and milk. The adrenals were removed transperitoneally under light ether anæsthesia with aseptic precautions. In some cases the gastrocnemius muscle of one side was removed simultaneously and treated as described below. When the animals were killed by decapitation after about 120 hours, they were with a few exceptions markedly adynamic. The organs were rapidly removed and placed directly upon a block of carbon dioxide 'ice'. They were weighed and minced in the frozen state. About 1 gm. of tissue was heated in 5 c.c. water just to the boiling point and then allowed to cool at room temperature. It was then kept in the ice-chest. Cozymase was determined in the supernatant fluid by the fermentation test with apozymase in Warburg vessels. The apozymase was standardized with a solution of almost pure cozymase (90–100 per cent).

Controls			Adrenalectomized		
Body weight (gm.)	Weight of brain (mgm.)	Cozymase (γ per gm. brain)	Body weight (gm.)	Weight of brain (mgm.)	Cozymase (γ per gm. brain)
♂ 187	1455	156	♂ 195	1188	94
♂ 202	1154	142	♀ 92	1199	126
♂ 215	1380	119	♂ 217	1320	144
♂ 220	1585	141	♂ 165	1317	151

♂ 245	1388	138			
♀ 123	1244	183			
		Mean 140			Mean 121

Experiments with a few animals failed to show any difference between adrenalectomized and control rats in the cozymase content of heart, liver, muscle and kidney. There appeared, however, to be a marked increase of cozymase content of the brain after adrenalectomy. That this was only accidental is shown by the accompanying table giving the values obtained in a series of 11 normal and 7 adrenalectomized rats. The cozymase content is given in γ cozymase per gm. fresh weight. The difference between the means is obviously not significant.

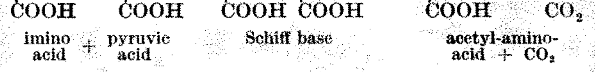
Mechanism of Enzymic Decarboxylation

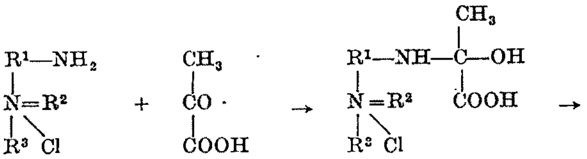
A THEORY of the mechanism of the enzymic decarboxylation of pyruvic acid is suggested, which, though not yet capable of strict experimental proof, is consistent with many recent observations.

Langenbeck[1] predicted the amine nature of cocarboxylase. He showed with various amines serving as carboxylase models that the first step of the catalysis is the formation of a Schiff base. Schiff bases have been postulated as intermediaries in several biological reactions, such as transamination[2] and synthesis of amino-acids[3-6], in the course of which they undergo intramolecular oxido-reductions. Of special interest, because it involves a decarboxylation of pyruvic acid, is the following mechanism of amino-acid synthesis originally proposed by Knoop[3,4] and experimentally corroborated by the recent work of du Vigneaud *et al.*[5,6]:



In this scheme pyruvic acid acts as hydrogen donator for the imino acid, being itself oxidized to acetic acid and carbon dioxide.

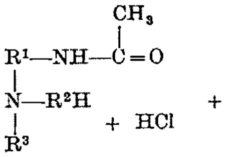
Besides possessing a free amino group, cocarboxylase contains pentavalent nitrogen which is capable of reduction[7]. The initial steps of decarboxylation may therefore be pictured by the following reactions involving an intramolecular oxido-reduction of the Schiff base primarily formed:



$$\begin{array}{l} R^1\text{—}NH_2 \\ | \\ N{=}R^2 \\ |\diagdown \\ R^3\ \ Cl \end{array} + \begin{array}{c} CH_3 \\ | \\ CO \\ | \\ COOH \end{array} \rightarrow \begin{array}{l} \qquad\qquad\ \ CH_3 \\ \qquad\qquad\ \ | \\ R^1\text{—}NH\text{—}C\text{—}OH \\ | \qquad\qquad\ | \\ N{=}R^2 \quad\ COOH \\ |\diagdown \\ R^3\ \ Cl \end{array} \rightarrow$$

cocarboxylase + pyruvic acid (I)

Schiff base (II)

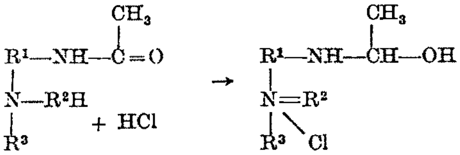


$$\begin{array}{l} \qquad\qquad\ CH_3 \\ \qquad\qquad\ | \\ R^1\text{—}NH\text{—}C{=}O \\ | \\ N\text{—}R^2H \qquad\qquad + \ CO_2 \\ | \qquad + \ HCl \\ R^3 \end{array}$$

acetyl-dihydrococarboxylase

(III)

Although the decarboxylating systems of yeast and animal tissues possess the same coenzyme, they differ in that the former converts pyruvic acid into carbon dioxide and acetaldehyde, whereas the latter, in common with certain bacteria, form carbon dioxide and acetic acid by an oxidative mechanism. On the basis of the proposed mechanism a natural explanation is possible if we assume that in animal tissues compound (III) is dehydrogenated to acetyl-cocarboxylase only by a specific carrier[8], whereas in yeast a second intramolecular oxido-reduction occurs resulting in the Schiff base of acetaldehyde (IV):



$$\begin{array}{l} \qquad\qquad\ CH_3 \\ \qquad\qquad\ | \\ R^1\text{—}NH\text{—}C{=}O \\ | \\ N\text{—}R^2H \\ | \qquad + \ HCl \\ R^3 \end{array} \rightarrow \begin{array}{l} \qquad\qquad\ CH_3 \\ \qquad\qquad\ | \\ R^1\text{—}NH\text{—}CH\text{—}OH \\ | \\ N{=}R^2 \\ |\diagdown \\ R^3\ \ Cl \end{array}$$

(III) (IV)

Besides accounting for the difference between yeast and animal carboxylase, the scheme outlined above is capable of explaining various other facts. It has been observed that acetic acid is very slowly metabolized by isolated animal tissues, yet it has been shown to be formed by the decarboxylation of pyruvic acid which is metabolized very vigorously. An 'active form' of acetic acid has therefore been postulated[9] which can be rapidly metabolized, probably by way of condensations leading to succinic, citric and acetoacetic acids. It is suggested that this 'active form' is identical with acetyl cocarboxylase.

It has recently been reported by Quastel and Webley[10] that the ability of propionic acid bacteria to oxidize acetic acid is greatly enhanced in presence of vitamin B_1. This can be explained by the assumption that this organism possesses the faculty of synthesizing the 'active form' of acetic acid, namely, acetyl cocarboxylase, from acetic acid and cocarboxylase.

The Releaser Concept in Bird Behaviour

LORENZ[1] has provided a wealth of data and analysis to show that many instinctive acts in birds are 'released' not by the external situation as a whole, but by some characteristic part of it. This greatly assists in explaining the evolution of plumage patterns and rhythmical movements in display in birds, particularly with regard to their 'improbable' and specific nature.

Recent work[2] on the British robin (*Erithacus rubecula melophilus* Hartert) suggests modification of the releaser concept. First, there is the obvious point (with which presumably Lorenz would agree) that the internal state of the bird must also be considered. Thus the copulatory behaviour of the male robin is released when the female assumes a characteristic flattened attitude. But sometimes the male does not copulate when the female assumes this attitude, and sometimes he tries to copulate without the female assuming this attitude; the former can be accounted for by an exceptionally weak, the latter by an exceptionally strong, copulatory drive in the male at the time.

The robin attacks all other robins intruding in its territory, and analysis of the external situation releasing this aggressive behaviour well illustrates Lorenz's point that a characteristic pattern can be the most important factor involved. For a mounted specimen of a robin lacking the red colouring on the breast was attacked much less often than a specimen reduced to just a bundle of red breast feathers and lacking head, wings, legs and back. However, analysis showed that no single factor releases aggressive behaviour, for the robin at times attacks (1) various other species of birds of most diverse coloration, chiefly in flight; (2) a mounted robin lacking red on the breast; (3) a bundle of red breast feathers: which three objects have no factor in common. Further analysis showed that the aggressive behaviour could be divided into three main reactions: (1) pursuit-flight, primarily elicited by a small bird flying away; (2) direct striking, primarily elicited by a stationary bird of approximately robin-shape (the presence or absence of red on the breast being unimportant); (3) threat-posturing, primarily elicited by a red breast. Hence the facts could almost be reconciled with the releaser concept provided that the aggressive behaviour was separated into three reactions, each with its own releaser. However, further work showed that this separation, while it undoubtedly existed, was only a tendency, and not a complete division, for, rarely, a mounted red breast was struck and a specimen lacking red on the breast was postured at.

Hence, at least in this case, the releaser concept is too simple. The general implications are important, for they suggest that releasers are not the fundamental units of bird behaviour. Rather, the bird reacts originally to a more general situation. At a later stage (later in evolution if the releasing complex is inherited, later in the life of the individual if it is acquired: this issue is not discussed here), the bird tends to react primarily (but not necessarily exclusively) to a characteristic part of the external situation. The characteristic part or pattern may then appear to 'release' the behaviour concerned; but it is not (at least always) the sole factor which will elicit the behaviour.

On the above view, releasers are considered to be specialized and secondary. The ability of birds to evolve releasing complexes is clearly of value to the species, and this modification of the concept in no way diminishes the importance of Lorenz's arguments on the nature and evolution of display patterns in birds, since it is agreed that a particular pattern is often the most important (though not necessarily the sole) factor eliciting a particular train of behaviour.

The robin's own mate apparently possesses all the main factors eliciting aggressive behaviour but is attacked extremely rarely and only mildly. This and other facts discussed in the paper cited show the complexity of the problem, which I have been unable to reconcile with any theory of behaviour. The partial separation of the behaviour into particular stimuli with particular responses suggests a mechanistic rather than a holistic interpretation; but the incompleteness of the separation shows a simple mechanistic interpretation to be inadequate.

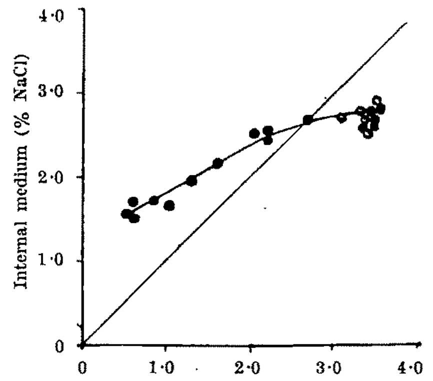
Osmotic Properties of the Common Prawn

IN a previous communication[1] I referred to the homoiosmotic behaviour of *Palæmonetes varians* and its ability to maintain hypotonicity in normal sea water. Further experiments on the osmo-regulatory mechanism of some Crustacea have revealed that the common prawn, *Leander serratus* (Pennant), is also definitely hypotonic when in normal sea water.

The blood of this prawn when taken from sea water has an osmotic pressure equivalent to 2·6–2·9 per cent sodium chloride, the difference between the external and internal media being round about 0·7 per cent. This osmotic pressure is more or less retained by the animals up to dilutions of about 2·5 per cent in the external medium; but in lower dilutions there is a steady decline. In laboratory experiments 0·5–1·0 per cent was the lowest range of salinities at which the prawns could live; and an osmotic pressure equivalent to that of 1·3–1·6 per cent sodium chloride would seem to be the minimum internal osmotic pressure compatible with life.

Compared with Palæmonetes, Leander has a higher osmotic pressure when in normal sea water, and the ability to maintain the osmotic pressure of the blood near the optimum is also much less developed in Leander, as may be seen from the accompanying graph. The difference between the highest and lowest values for the blood of Leander in different dilutions is nearly 1·5 per cent, while the corresponding difference for Palæmonetes is only 0·5 per cent.

Studies on the rate of change of osmotic pressure when prawns are put in dilute sea water have shown that the reduction of the internal osmotic pressure goes on steadily and slowly during the first 14–24 hours, but after the lowest value has been reached there is a slight rise. It is worthy of note that the rate of change of osmotic pressure is different in individuals of different sizes. Young prawns 45–65 mm. long respond to external osmotic changes more speedily than larger ones. The ability to live with a low osmotic pressure of the internal medium is also more pronounced in them than in full-grown individuals.



RELATION BETWEEN THE OSMOTIC PRESSURE OF BLOOD AND THE EXTERNAL MEDIUM OF *Leander serratus*.
Values in per cent sodium chloride. Abscissæ, sea water; ordinates, blood. Straight line indicates where points would fall if blood and medium were isotonic.

Leander serratus is a littoral species abundant in the southern parts of the North Sea and in the Mediterranean[2]. Though it is able to live in places where the salinity is slightly lower than that of the sea as observed at Plymouth, its habitat is essentially marine; but the osmotic behaviour of *L. serratus* is most unusual for a marine invertebrate. It is of great interest, since certain prawns like *Leander longirostris* M. Edw. are known to migrate many miles up rivers[2] and many tropical species are known to be typical brackish-water and freshwater inhabitants[3]. If the osmotic properties of *Leander serratus* are shared by other species (and it seems very likely), it would explain their peculiar habits and distribution. The physiological evidence would seem to be in favour of considering this species of Leander as having taken secondarily to marine life, since its osmotic behaviour is so unlike that of most other marine invertebrates that have developed powers of osmo-regulation.

Utilization of Nitrogen by *Ophiobolus graminis*

THE survival period of the fungus *Ophiobolus graminis*, causing the 'take-all' disease of wheat, in infected wheat straw buried in the soil is increased by the application of nitrogen in such forms as calcium nitrate, ammonium nitrate, ammonium sulphate, ammonium carbonate, and dried blood[1,2]. I have recently suggested[2] that these sources of nitrogen are directly utilized by *O. graminis*, which is thereby enabled to decompose more of the carbohydrate material of the straw, and hence to prolong its existence. Fellows has claimed[3], however, that *O. graminis* is unable to utilize nitrates or ammonium salts, and can assimilate nitrogen only in certain organic forms. His claim is invalidated by the experiments of Padwick[4], using a very similar synthetic medium to that employed by Fellows, but with the addition of a growth-promoting factor. In the presence of a growth-promoting extract obtained from carrots, growth of *O. graminis* was increased four-fold by the addition of 0·15 per cent of nitrogen as sodium nitrate to the medium.

The results of a recent experiment here support those of Padwick. 6-gm. portions of chaffed wheat straw were bottled with the addition of 24 ml. of water or calcium nitrate solution. The calcium nitrate series received 0·25 gm. of nitrogen per 100 gm. air-dry straw. The bottles were plugged and autoclaved for 30 minutes at 15 lb. pressure on three successive days, inoculated with a pure culture of *O. graminis*, and incubated at 25° C. The loss in dry weight in the two series with and without additional nitrogen was as follows (each determination is a mean derived from three bottles):

	Percentage loss in dry weight (oven-dry basis)	
	After 3 months	After 6 months
No additional nitrogen	21	28
With 0·25 gm. nitrogen as calcium nitrate	27	33

Determinations of nitrate nitrogen in the calcium nitrate series, kindly made for me by Mr. R. G. Warren, of the Department of Chemistry, were as follows:

Sterilized but not inoculated control—240 mgm. nitrate nitrogen per 100 gm. air-dry straw.

Inoculated and incubated for 3 months—13 mgm. nitrate nitrogen per 100 gm. air-dry straw.

Inoculated and incubated for 6 months—0 mgm. nitrate nitrogen per 100 gm. air-dry straw.

These results show that a pure culture of *O. graminis* growing on sterilized wheat straw can utilize nitrate nitrogen, and hence support the conclusions of Padwick[4].

Occurrence of Some Off-shore Amphipods in the Littoral Zone

IT has been pointed out by various investigators that *Echinus esculentus* L., an animal usually confined to off-shore waters, is found in some places in the littoral zone. Reid[1] showed that it occurred intertidally only on those coasts washed by the North Atlantic Drift, while elsewhere it was confined to deeper waters.

During a period of collecting in August at Oldany Bay Harbour, near Drumberg, Sutherland, *Echinus esculentus* was found intertidally. But it is of interest to note that the following amphipods were also found above low water of spring tides beneath stones and in algæ (Dictyosiphon sp.).

Gammaridea: *Ampelisca spinimana* Chevreux, *Harpinia antennaria* Meinert, *Leucothöe spinicarpa* (Abildg.), *Coremapus versiculatus* Norman.

Caprellidea: *Phtisica marina* Slabber, *Caprella acanthifera* Leach.

A search of the literature has so far shown that, with two exceptions, these amphipods have only been recorded in deep water or below the tidal zone. The two exceptions are *C. versiculatus* and *C. acanthifera*, and it is significant that these records are from the Clyde area and Lough Ine, both of which regions are bathed by Atlantic water. This discovery is of interest and suggests that the phenomenon shown by Echinus may be of a more general character than is supposed. A study of the intertidal distribution of other animal groups round the British Isles might prove of value.

Scientific and Technical Literature and Information

AMONG the important suggestions made in the editorial in NATURE of November 25 is included the desirability of establishing a new organization which would, among other things, "establish a system of co-ordination among the various provincial libraries of the university and research types". Although it is stated that "the National Central Library is still functioning as a clearing-house for demands for books on loan", it is apparently not realized that this Library is already acting as the national centre for the inter-library lending of books and periodicals, not only between libraries of "the university and research types", but also between libraries of all types, among which must be included our larger public libraries, which frequently contain—and lend—scientific and technical books not available in any other library in the British Isles.

It would appear to be extravagant and unnecessary to set up a new organization to do work which the National Central Library is already doing and for which it has the necessary machinery, even if this is still far from perfect. The service of the Library is used by Government departments, the universities, and almost every library in the British Isles. In normal times it is used also by libraries throughout Europe and elsewhere. The extent of the service is illustrated by the fact that, in addition to the books on its own shelves, the Library has access to more than 21,000,000 books in other libraries in the British Isles. The libraries lending and borrowing through the National Central Library include many of the leading scientific and technical libraries in the country.

It is true, as is stated in the article, that the National Central Library depends upon the Science Library for many books and periodicals—in fact the value of the co-operation of the Science Library cannot be too strongly emphasized—but it is only fair to the other scientific libraries and to the National Central Library's own stock to point out that last year only approximately three per cent of the scientific and technical books lent were obtained from the Science Library.

It is suggested that a union catalogue of war-time holdings of important foreign periodicals should be compiled, but it is not pointed out that, in addition to the entries in many printed union and other catalogues, the National Central Library has tens of thousands of manuscript entries of periodicals in British libraries. This information is constantly being brought up to date.

Experience so far suggests that no great difficulty is likely to arise in buying current numbers of foreign, including German, periodicals through the authorized agents. It may not, therefore, be necessary to establish "a central body" for this particular purpose.

As is now well known, the service of the National Central Library is available to any person, provided that he applies for books through his university, public, or other library, and not directly to the National Central Library.

L. NEWCOMBE.
(Librarian).

National Central Library,
Malet Place,
London, W.C.1.

THE services provided to the scientific and technical research worker by the National Central Library are too well known to need emphasis in the present emergency. So far as text-books and pre-war volumes of periodicals are concerned, these services will doubtless find increasing utilization during the War. However, the original editorial more specially concerned itself with the supply and use of current issues of scientific and technical periodicals, especially European publications. The only portions of Colonel Newcombe's memorandum that are relative to this specific problem are his statements that the entries in the National Central Library relating to holdings of such periodicals by British libraries are constantly being brought up to date, and his optimism concerning the facilities for obtaining European periodicals at the present time.

Regarding the first claim, it may be true that, from time to time, the entries relating to holdings of periodicals are revised by the libraries concerned, and copies of the revisions incorporated in the archives at the National Central Library. Nevertheless, it is a well-known fact that contributor libraries to union catalogues of holdings are exceedingly dilatory in communicating information that reflects the deficiencies of their stocks, and this is especially true of current volumes. All librarians naturally hope to fill any lacunæ that arise, and hesitate to revise even their own catalogues until the entries are closed up finally. It is quite certain that, unless the urge to revise entries and betray gaps is stimulated by a prospect that the gaps may be filled from some 'pool', librarians will see no reason to notify the National Central Library of the deficiencies in their holdings of current volumes.

As regards Colonel Newcombe's optimism about present facilities for purchasing European periodicals, it is not irrelevant to point out that already the National Central Library has taken the precaution of removing its records to a relatively obscure site, and has thus provided evidence of a dislocation that may have been temporary in some aspects, but is permanent in others. It can scarcely be said to have facilitated the operations of this particular centre. There are, however, many other aspects of this problem of supply. Many libraries have closed down; many others have seen their periodicals, previously obtained by presentation or exchange, come to an abrupt termination in the middle of volumes; most libraries have to economize in their purchases. The effects of these three factors alone will render the National Central Library's union catalogue of doubtful efficacy in regard to holdings of current issues of European periodicals unless drastic revisions are made therein. Finally, we have to consider the possible extension of hostilities to include those neutral countries that are at the moment serving as sources of supply for these periodicals, the effects of intensive hostilities at sea, and the possibility that sooner or later extensive air-raids over Britain may occur.

THE WRITER OF THE ARTICLE.

Archæology in the U.S.S.R.

IT would be a pity if dislike of the Soviet's foreign or domestic politics should lead men of science to take an unduly gloomy view of the position of archæology in Russia[1]. Prof. Tallgren's last visit to the U.S.S.R. coincided with mine in 1935, and since then many changes have supervened, one may hope for the better. For example, in 1936 a new periodical, *Sovietskaya Archeologiya*, better printed and illustrated than its immediate forerunners, began to appear, to make up a little, admittedly inadequately, for the deficiencies in publication which Tallgren deplored.

The editorial in No. 1 might indeed reinforce his apprehensions—"La lutte implacable contre les écrits pseudo-scientifiques fascistes en matière d'archéologie, le dévoilement incessant des falsifications fascistes des faits archéologiques constituent le devoir direct des archéologues soviétiques qui édifient la véritable science objective"; "La lutte sans merci contre les altérations de tout genre du marxisme-léninisme"—and similar sentiments were discouraging. However, the introduction to No. 2 is devoted to a repudiation of the scholasticism No. 1 apparently approved, a rehabilitation of migrations, the typological method and other devices and an elaboration of the theme "Les recherches historiques exigent une étude approfondie, méthodique et objective des sources premières au lieu que le schématisme corrompait la pensée des historiens, les habituant à mépriser les faits".

Far from making a gulf "completely effective against Western archæological thought", the Institute for the History of Material Culture in the Academy of Sciences seems to welcome exchanges with archæological societies in Great Britain and with individuals, including the writer. "Gentile", "pre-class", . . . may be inconvenient categories; I doubt if they are really more deceptive than the terms "neolithic", "Bronze Age" as used in English as late as ten years ago. Prehistoric archæology, being based so largely on a study of tools and weapons, naturally lends itself to a "materialist" interpretation. That does not exclude a study of non-economic activities even in Russia, as for example Zamiatnin's long discussion on fertility rituals in his memoir "Gargarino".

V. GORDON CHILDE.

Department of Prehistoric Archæology,
University, Edinburgh.

[1] NATURE, 144, 971 (1939).

PROF. V. GORDON CHILDE utters a timely protest against "dislike of the Soviet's foreign or domestic politics" leading men of science "to take an unduly gloomy view of the position of archæology in Russia". It was, however, precisely with the view of deprecating any political colouring whatsoever, and of whatever shade of opinion, in scientific matters that protest was made in these columns against the way in which political doctrine under the Soviet Republics had not only affected archæological theory, but had also intervened to check international exchange in scientific research.

Attention was then directed to a specific instance of such interference by which an end has been put to Prof. Tallgren's work—this at a date subsequent to that to which Prof. Childe looks for the appearance of some signs of improvement. Even more abhorrent to the spirit of scientific investigation is the regimentation and even 'liquidation' of the individual, from which archæology, with other sciences, in the U.S.S.R. has suffered severely. This is no question of like or dislike of a political policy as such.

THE WRITER OF THE NOTE.

Points from Foregoing Letters

Evidence, in the form of a cloud-chamber photograph, is given by E. J. Williams and G. E. Roberts for the transformation of mesotrons into electrons. This bears out the supposition that the mesotron is identical with the particle assumed by Yukawa in his theory of nuclear forces and β-disintegration.

A. H. Wilson and F. Booth have calculated the probability that, when a fast meson collides with a nucleus, a very energetic γ-ray will be emitted. They find that the cross-section is proportional to the energy of the meson, and that for very high energies the energy loss is mainly due to the emission of γ-rays. The bearing of this upon the cascade showers in the atmosphere is discussed.

The known nuclear energy levels of ^{10}B, ^{26}Mg and ^{223}Ac*X* are interpreted by K. M. Guggenheimer as eigenvalues of the rigid rotator, which can thus be applied to nuclei. The moments of inertia are in accordance with the assumption of equal nuclear density.

Quantitative clinical observations by J. S. Mitchell, under conditions with equalized depth dose distribution, show that 0·7–0·8 r. unit of X-radiation of effective wave-length 145 X.U. is equivalent, in the production of moist desquamation of human skin, to 1 r. unit of γ-radiation of effective wave-length 15 X.U. Theoretical considerations suggest that this result cannot be attributed entirely to the exceptional histological and chemical structure of skin.

A mechanism for the enzymic decarboxylation of pyruvic acid is proposed by H. Weil-Malherbe involving the formation of a Schiff base from cocarboxylase and pyruvic acid followed by an intramolecular oxido-reduction leading to acetyl-dihydrococarboxylase. It is suggested that this compound is oxidized in animal tissues and in certain bacteria by a specific carrier, whereas it undergoes a second intramolecular oxido-reduction with yeast carboxylase resulting in the formation of the Schiff base of acetaldehyde. Acetyl cocarboxylase may be identical with the 'active form' of acetic acid postulated for animal tissues.

Analysis of aggressive behaviour in the British robin by D. Lack shows that it can be divided into three main reactions, each primarily elicited by a different external factor; but this division is only partial. While colour pattern is particularly important, it is not the sole releasing factor, and, in general, releasers are considered specialized, and not fundamental, units of bird behaviour.

N. K. Panikkar finds that, like Palæmonetes, the common prawn *Leander serratus* is definitely hypotonic when in normal sea water, though it is less homoiosmotic than the former. Its osmotic behaviour is unusual for a typical marine invertebrate and is of interest when the habits of allied species are considered. The osmotic properties would seem to indicate its having taken secondarily to marine life.

S. D. Garrett reports assimilation of nitrate nitrogen by a pure culture of the fungus *Ophiobolus graminis* growing on sterilized wheat straw plus calcium nitrate.

C. B. Goodhart and Richard Harrison report the occurrence of six off-shore species of amphipods in the littoral zone on the north-west coast of Scotland.

War-time co-ordination of library resources, as advocated in a recent issue of NATURE, is discussed by the librarian of the National Central Library. He states that the union catalogue housed in the Library and relating to periodicals in British libraries is subject to continual revision, and that the difficulty of obtaining foreign periodicals in war-time has been exaggerated. In reply to these comments, it is pointed out that revision of entries in union catalogues of periodicals is generally very tardy and imperfect, and that the present period will enhance these imperfections. Reasons are given for anticipating further dislocation and interference with supplies, as compared with peace-time.

RESEARCH ITEMS

New Neolithic Site in Ulu Kelantan, Malaya

THE results of the partial excavation of a rock-shelter at Gua Mĕntĕri on the banks of one of the tributaries of the Sungai Nenggiri have been described by H. D. Noone (*J. Fed. Malay States Mus.*, **15**, 4; 1939). The shelter is about 50 yards in length, 20 yards in height, and of an average breadth under cover of 9 or 10 yards. Two trial trenches were dug, but barely 10 per cent of the area available for excavation was touched. Nevertheless, finds were exceedingly numerous. Except where removal was imperative, they were so far as possible covered in again pending the systematic excavation which the importance of the site demands. It affords stratigraphic evidence for the neolithic period, which is urgently needed; and in the human skeletal remains from the burials it will throw light on the at present obscure problem of the population which carried the neolithic culture into Malaya. The grave goods included pots in rows, and disposed in one instance in threes, one inside the other in the inverted position. The eight complete specimens now recovered are unique as evidence of the character of the neolithic pottery, previously known only from sherds, except for a few complete pots from open sites found without associations or stratification. The trial excavations of two trenches revealed three cultural layers, of which the uppermost at a depth extending to 2½ ft. below red clay was rich in relics of a fully developed neolithic, among which three polished axes were found, preceded, it would appear, by an earlier developmental period. This, in turn, was preceded by a cultural layer of an intermediate character marked by the occurrence of numbers of worked flakes of a black stone, which when struck behaves like flint. The earliest cultural level contained palæolithic implements (Hoabinian). In this three intrusive (neolithic) burials with grave furniture were found, the lowest at a depth of five feet below the red clay. Apart from that associated with the burials this lowest level contains no pottery.

A New Drug for Pneumonia Treatment

THE search for new drugs for combating certain infections continues. A few years ago sulphanilamide was introduced and proved of considerable service in the treatment of sepsis due to the streptococcus, and a couple of years ago sulphapyridine (M. and B. 693) was discovered to be of great value for the treatment of pneumonia, cerebro-spinal fever, and other infections caused by the coccoid group of microbes. It is now announced by Science Service of Washington, D.C. that another drug, sulphathiazole, has been developed in the Squibb Institute for Medical Research, New Brunswick, for the treatment of pneumonia. It is stated that it is even more efficacious against this disease than sulphapyridine, that it is safer and has less toxic effect than the latter.

Control of Puerperal Sepsis

AN important memorandum on this subject has been issued by the Ministry of Health (Memo. 226/Med. H.M. Stationery Office. 2*d*. net). Its object is "to explain the nature of puerperal sepsis, how it is spread, and how to identify and group the streptococci responsible". Actually, little is said about puerperal infection in general, the pamphlet being restricted to infections due to the class of microbes known as hæmolytic streptococci, which, however, do not account for more than half the cases of puerperal infection. Details are given of the sources of streptococcal infection, and of the methods of detecting it in patient, midwife or nurse, and of the procedure to be adopted when a source of infection is detected. Finally, a description is given of the laboratory methods required for the isolation and identification of the hæmolytic streptococcus.

Insects of Greenland

STUDENTS of animal distribution will welcome the recent contribution by Kai J. Henriksen entitled "A Revised Index of the Insects of Greenland". Published in *Meddelelser on Grønland* (**119**, No. 10, 111; 1939), it is obtainable from Messrs. C. A. Reitzels of Copenhagen, price Kr. 5.00. It appears that more than twenty years have elapsed since the last list of Greenland insects was published. During that period both English and Danish collecting expeditions have added materially to what is known of the Greenland insect fauna. The Collembola, for example, have been well studied and now number forty-one species. Only a single species of may-fly and no dragonflies have so far been recorded. Among the fifty-four species of Lepidoptera only four are butterflies. Of particular note is the Noctuid moth *Rhyacia occulta* L., the larvæ of which are often pests of the grassland. In two peat bogs at the head of the Ameralik Fjord an entire layer of pupæ of this insect is recorded, and it bears witness to an outbreak of *R. occulta* in bygone times. Coleoptera are poorly represented and number only forty-four species while some of them, notably Cerambycidæ, are introduced forms. Among the Hymenoptera the Parasitica are relatively very numerous, but little idea can be framed as to their hosts. Records of sixty-five species of the Ichneumonidæ alone are given, whereas the only Aculeata recorded are two species of bumble bees. Of the Diptera some two hundred and seventy-five species are listed, Nematocera being the best represented. Mr. Henriksen's memoir concludes with a bibliography of about eighty references, the majority being to writings in the English language.

Hormones and the Garden

THE discovery of growth-promoting compounds in plants brought new opportunities of horticultural propagation. Marked stimulation in the rooting of cuttings of many species can be brought about, but a curious crop of failures has still to be explained. M. A. H. Tincker, with the assistance of C. H. Unwin, has studied the action of a number of such substances upon a wide range of plants which can be propagated by cuttings. Their most recent results (*J. Roy. Hort. Soc.*, 64, Pt. 12; December 1939) indicate that sixty-one species of those which were tried propagate more readily with treatment, whilst twenty-nine species still defy the propagator. The growth-promoting substances can be mixed with talc and applied satisfactorily in powder form—a great convenience.

Vitamin B_1 (aneurin) alone did not appear to stimulate rooting, but it did increase the percentage of rooted cuttings in a third of the total experiments. The most valuable substances for propagation were found to be (1) indolylbutyric acid, (2) tetrahydronaphthylideneacetic acid, and (3) a mixture of (2) with 3 : 4-dihydro-1-naphthylacetic acid. Some species responded to (1), and others to (2), with equal effect, and the behaviour of (3) approximated closely to (2). The paper gives numerous results of the individual calibre which is urgently needed in this new practice of scientific horticulture.

Sex-chromosomes in Cimex

C. D. DARLINGTON (*J. Gen.*, 39, 101–136 ; 1939) has examined the behaviour of the sex-chromosomes during meiosis in Cimex. In the male there are 13 pairs of autosomes, a *Y*-chromosome, together with a variable number of *X*-chromosomes ranging from 2 to 12 according to the species and the culture. At first metaphase, the *X*-chromosomes do not pair but divide as univalents. At the second division, the autosomes form a peripheral ring and the sex-chromosomes congregate in the middle of the equatorial plate. At second anaphase, the *Y*-chromosome passes to one pole and usually all the *X*'s pass to the other. This is believed to be brought about by repulsion resulting from a close approximation in the centre of the equatorial plate. Evidence suggested that the centromeres of the autosomes have polarized centromeres at second metaphase, while the *X*-chromosomes have not. The evolution of the sex-chromosome mechanism in Heteroptera is analysed, and it is shown how the peculiar behaviour of the *X*-chromosomes results from differential precocity.

Effect of X-rays on *Drosophila subobscura*

A. L. M. CHRISTIE (*J. Gen.*, 39, 47–60 ; 1939) has compared the effects of X-ray radiation on *D. subobscura* with those on *D. melanogaster*. The frequency of lethal mutations induced by X-rays is about equal in the two species, but many more visible mutants occur in *D. subobscura* at a given X-ray dose. It is noteworthy that *D. subobscura* lies between *D. melanogaster* and *D. funebris* in regard to the type of mutation produced. Twenty-eight mutants are described, and a rough map of the *X*-chromosome, approximately 120 units long, is given.

Mycological Taxonomy

THE *Transactions of the British Mycological Society* of October 1939 (23, Pt. 3) contains two papers which offer detailed contributions to the exact recognition of fungal species. J. A. Nannfeldt, of the Institutionen för Systematisk Botanik, Uppsala, describes a second batch of fifty type specimens of British inoperculate Discomycetes. This is part of a critical evaluation of species in this group, and deals with an alphabetical arrangement from Cenangium to Velutaria. The correct name of each species in the light of modern knowledge is indicated, and an adequate list of synonyms appears for each. Miss E. M. Wakefield writes the second contribution, on "Nomina generica conservanda". She sets forth the deliberations of the Society's Nomenclature Committee with regard to such generic names as now appear to have little use, after recent findings have excised well-defined groups. Peziza, for example, a generic name established by Fries in 1822 to include a large group, cannot now be used to express more than a few species. The Committee has made definite recommendations for the retention of thirteen names in the lists published as a supplement to the International Rules, 1935. A new species of fungus, *Phleospora Dodonææ*, is also described by R. M. Nattrass in the same volume. It was found as a parasite upon a hedge of *Dodonæa viscosa* in Cyprus.

Life-Histories of Coprophilous Fungi

DETAILS of the life-histories of coprophilous Pyrenomycetes have been somewhat lacking in the past. Literature dealing with the Sordariaceæ and Chætomiaceæ, which are principally concerned, consists largely of descriptions of perithecia, asci and spores, or systems of classification. W. M. Page has grown, upon artificial media, sixteen species belonging to the genera Sordaria, Podospora, Philocopra, Sporormia and Chætomium, in order to obtain more definite information as to their life-histories (*Trans. Brit. Mycol. Soc.*, 23, Pt. 3, October 1939). The perithecium originates from a coiled hypha in all but two of the sixteen species. The exceptions, two species of Sporormia, are notable in that the perithecium initial divides in three dimensions, probably an indication of evolutionary superiority. Microconidia were observed in *Podospora anserina* and *P. minuta*; many other details of spores and spore discharge appear in the paper.

Research in Agricultural Meteorology in India

IN addition to the brief summary of the more recent activities of the Agricultural Meteorology Section of the India Meteorological Department that is included in the Department's general report for 1938–39, a more detailed account has recently appeared of the Section's work in 1937–38 in its annual report for the latter period. This report includes a description of an improved portable sensitive galvanometer with thermocouple junctions for measuring plant temperatures, made by the Laboratory Apparatus Works, Poona. One of the thermocouples is kept immersed in water of known temperature inside a thermos flask, and the other is inserted into the stem of the plant. When used in the field the instrument is carried on a metal tripod and is levelled with the aid of a spirit-level. A number of soil evaporimeters were in use in which a 5-in. diameter cylinder of soil is kept with its bottom end in contact with the water in a reservoir at a depth of 6 in., or 1 ft., etc., down to 3 ft., in order to study the evaporation from soil surfaces with subsoil water at these depths. Other instruments included an alarum which could be set to sound when air temperature had fallen below a certain level, so that a farmer who installs the device can take precautionary measures against frost damage on hearing the alarum. It has been found that there is an increasing demand for these, vine and sugar growers being among those who have found it useful. Investigations into the disposal of solar radiation and rainfall at the surface of the ground were continued at the Central Agricultural Meteorological Observatory, and also the exchange of water vapour between soils, plant materials, seeds, etc., on one hand and the atmosphere on the other. It was found that all the last-named surfaces yielded moisture to the atmosphere during the hottest hours of the day and received back moisture at night. On the statistical side, sampling studies on the growth and yield of various crops at Poona and other places were continued.

SALT ABSORPTION OF PLANTS

BY PROF. H. LUNDEGÅRDH,

INSTITUTE OF PLANT PHYSIOLOGY, ULTUNA, UPPSALA

IN a communication to NATURE I outlined an electrochemical theory of salt absorption by plant roots[1]. Later, Hoagland and Steward criticized not only the theory itself but also the data on which it was founded[2]. From the article by Hoagland and Steward the general reader might get the impression that the experimental basis of my theory is doubtful. I therefore venture to give a short recapitulation of the work of the Institute of Plant Physiology in Ultuna, Uppsala.

Since 1927 our work has been chiefly devoted to the problems of salt absorption in higher plants. In 1927–32 extensive quantitative investigations[3] on salt absorption showed a wide application of the rules of colloidal chemistry to the process of uptake and transport of cations, and an elaborate study of the antagonistic effects was published in the year 1934 by H. Burström[4]. Also the specific velocity of the anions was demonstrated in earlier papers[5]. The principle of the individual absorption of cations and anions postulates an ion exchange at the surface of the absorbing cell or organ, a well-known fact stated in modern text-books of plant physiology[6]. The existence of such an ion exchange suggested the study of the total ion balance in the boundary between root and medium, including the HCO_3 ions, coming from the expired carbon dioxide. After a preliminary study on this balance[7], it seemed necessary to determine quantitatively the respiration during the ion absorption. These studies soon showed a marked relation between the intensity of root respiration and the amount of absorbed salts[8]. In view of our previous experience in the individual absorption of ions of opposite charge, we tried to correlate the respiration with the uptake of cations and anions. In these experiments one anion, for example, NO_3 or Cl, was combined with a number of cations of different absorption velocity, and also the concentration of the salts was varied. The respiration showed a marked relation to the amount of absorbed anions, and thus the conception 'anion respiration' arose (1933). Apart from the anion respiration the root tissue, as well as all living organs, shows also a fundamental respiration. The total respiration is the sum of the fundamental and the anion respiration[9].

Parallel to the work of Lundegårdh and Burström, Steward and Hoagland and collaborators showed that 'aerobic metabolism' is essential to salt absorption. But they were not able to find either quantitative relations or an individual absorption mechanism of anions. The cause of these negative results of Hoagland and Steward is twofold. They limited themselves to a very restricted combination of cations and anions; then their choice of material and experimental technique was inappropriate. In studying quantitatively a physiological process it is very important to choose an organ which is exclusively designed to effect this process. The root system of grass plants is an intensive working absorption machine, which pumps salts into the lower parts (that is, the region of root hairs) and transports them into the upper parts. The bleeding sap which issues from the top of a cut root system contains salts in a much higher concentration than the solution from which these salts are pumped[10]. Hoagland and Steward used either slices of very slowly absorbing storage tissue, or ignored roots which were submerged in the solution. In the former case the ion absorption is too small to render possible an accurate determination of the coupled respiration process, because this will be covered by the variations of a considerable fundamental respiration. In the latter case the root pieces will pump in salts from the solution at the lower end and pump them out again at the top, and the amount stored up in the tissue will for this reason give an incorrect picture of the absorption intensity. Recently, van Eijk[11], at the University of Amsterdam, repeated the experiments of Lundegårdh and Burström on roots of a plant of a type quite different from wheat, namely, *Aster tripolium*. Van Eijk confirmed the "Lundegårdh principle of salt respiration". He presented, furthermore, a detailed criticism of Steward's experiments and draws the following conclusion (in translation): "Steward's criticism of Lundegårdh's investigations cannot be sustained, because it is built upon experiments, the method of which is insufficient to demonstrate the anion respiration or on experiments with subjects which *a priori* must cause negative results"[12].

I have repeatedly tried to explain that in the case of the roots of a number of plants the absorption mechanism will function fairly well, if respiration energy is supplied only when anions are absorbed[13]. The protoplasmic colloids and also the free surface of the root cells have negative electrical charge and thus attract cations. This absorption potential will lead to an accumulation of cations in the protoplasm. But this accumulation stops when the absorption surfaces are saturated. If now anions are simultaneously absorbed by means of an energy-expending respiration process, these anions will, when they come into the cells, remove cations from the absorption surfaces and cause an accumulation of neutral salts. This theory implies also that anions, for example, of organic acids, are produced within the cell itself. In this case the cation absorption will proceed, even if no anions are absorbed from the outside. But the metabolic activity through which organic acids are produced should not be confused with the anion respiration process which enables inorganic anions to enter the cell. This is a very important distinction. Burström has shown that it is possible to distinguish experimentally between the process by which NO_3 ions are absorbed in the root and the chemical mechanism of NO_3 reduction[14]. I showed recently that manganese is a catalyst for fundamental respiration processes, but fails to influence the anion respiration and anion absorption[15]. Burström discovered that manganese is essential for the reduction of NO_3, but has no influence on the NO_3

absorption process[16]. Earlier investigations by Lundegårdh and Burström[17] demonstrated a remarkable difference in the sensitivity of the fundamental respiration and of the anion respiration to cyanide and metallic poisons. Hoagland and Steward seem to have overlooked these results, which prove the possibility of dividing up the 'aerobic metabolism' into at least two distinct groups of processes :

(1) the fundamental respiration complex, which is characterized by its insensitivity to cyanide and the catalytic action of manganese, and

(2) the anion respiration, which is very sensitive to cyanide, but independent of manganese.

Very important is Burström's result that nitrate reduction persisted in crushed root material, whereas the absorption of NO_3 from the solution takes place only if the living organization is intact[18]. This observation conforms with my theory of ion absorption, which postulates the existence of an electrically charged absorption surface and an internal respiration mechanism, which transports the ions to the interior of the cell or organ[19]. The theory assumes a polarity (that is, a one-sided movement of substances) which, of course, will be destroyed if the living substance is crushed.

The complex of fundamental respiration is to be considered as the sum of a number of exothermic chemical processes, which build up cell substance, for example, protein synthesis and growth material of any kind. Some ions, for example NO_3, no doubt participate in both respiration systems : the anion respiration during the uptake, and the fundamental respiration during the reduction and proteinization process. If the cation NH_4 produces an acceleration of the total respiration of the root, as Hoagland and Stewart claim[20], this might be due to an increase in the fundamental respiration complex, because protein synthesis involves a partial breakdown of carbohydrates. Cations which do not interfere with organic chemical processes within the cell, for example, alkali metals and alkaline earth metals, are to a limited extent absorbed from bicarbonates without any increase in the respiration[21].

The coefficient $k = \frac{Ra \text{ (anion respiration)}}{A \text{ (anion absorption)}}$ is fairly constant, if A is varied by means of variations in the concentration of one single salt. If the effect of salts with the same anion but different cations is studied, k changes somewhat with the type of cation. As a rule k increases with the absorption power of the cation[22]. The circumstance that the quotient $\frac{A \text{ (= absorbed anions)}}{M \text{(= absorbed cations)}}$ also increases with k is an expression of the fact that k is a function of the work which the living organ has to perform in the absorption process[23]. Work can also be expressed in terms of electro-chemistry, and this was the reason why I started a series of observations of the boundary potential between the root and the solution. The results of these investigations have been fully described in two papers[24], and the studies are being continued. Hoagland and Steward also criticize these results.

Hoagland and Steward claim that the potential measurements are performed on "ill-defined" surfaces. I do not know whether they consider the boundary between root epidermis and nutrient solution to be nebulous and unfit for producing an electrical double layer. Speaking in well-known terms of physical chemistry, the existence of electrical potential differences, not only between the root surface and the solution, but also between cell sap and protoplasm, between nucleus and protoplasm, etc., is self-evident. Bio-electrical currents arise everywhere as a consequence of such boundary potentials, if a circuit is closed, and countless measurements of such bio-currents have been made. In an organ the cells are coupled wall by wall and the opposite charges therefore to a large extent neutralize one another. For this reason observed potentials arise, in the majority of the cases, in the boundary between the cell or organ and the electrode. In my experiments the problem was settled by the fact that a sudden change in the electrode solution caused an instantaneous change in the boundary potential, the height of which corresponded with what was electro-chemically to be expected. The boundary between the tissue of the root tip and the solution is consequently well defined, and its behaviour corresponds with well-known laws of physical chemistry.

From a thermo-dynamical point of view, the existence of a boundary potential at the surface of the root must act as a regulator upon the ion absorption (exchange) from the surrounding solution. A number of earlier investigations on animal tissue and also on roots[25] show a distinct relation between respiration and potential. Unpublished results from this laboratory confirm the existence of such a relation and the fact, postulated in my letter to NATURE, that a fraction of the root respiration (that is, anion respiration) causes an increase of the positive charge (a lowering of the negative charge) of the root surface, thus facilitating the absorption of anions.

Hoagland and Stewart claim that my theory of ion absorption means an "over-simplification of a very complicated problem". The experimental work of this Institute shows, on the contrary, that the absorption of inorganic ions is far more complicated than earlier investigators, among them Hoagland and Steward, believed.

BY PROF. D. R. HOAGLAND, UNIVERSITY OF CALIFORNIA

AND

DR. F. C. STEWARD, UNIVERSITY OF LONDON

Our earlier article directed the attention of the general reader to two independent series of investigations which have been in progress in different laboratories for several years. The combined investigations are extensive and deal with a variety of plant materials and environmental conditions. These apparently divergent investigations yield a consistent general picture of the process of salt uptake in plants, and we are not persuaded by Prof. Lundegårdh's arguments that this picture can be dismissed by the general reader. Our view is that salt accumulation involves vital processes in a more complex and intimate manner than would be suggested by Prof. Lundegårdh's discussion with its reference to principles expressed "in modern text-books of plant physiology" and "well-known terms of physical chemistry".

Prof. Lundegårdh's rejoinder mainly recapitulates his own earlier work. It will be recalled that we had raised the following general points.

(1) Any view of the metabolic processes concerned with salt uptake which has as its dominant feature carbon dioxide production, and especially a limited phase of carbon dioxide production conditioned only by anion uptake, is too restricted. Other vital processes are also concerned, perhaps more fundamentally. Pre-eminent are metabolic properties which are characteristic of cells still able to grow; but which are still difficult of quantitative expression.

(2) There is not, in our view, the sharp distinction in the relation of metabolism to the uptake of cations and of anions, described by Prof. Lundegårdh.

(3) The effects of salts on respiration—undoubted alike for roots and a variety of storage organs—are not related specifically to anion absorption; cations also exert an influence, which is the predominant one for some tissues, and the effects of differential absorption of cation and anion introduce additional factors.

(4) The storage tissue experiments deal with cells uniform in origin, subject to rigid control, in which the capacity for further growth is known. Root systems can never provide such uniform material; but in the experiments of Hoagland and Broyer special methods yielded root material which was replicated with accuracy well within the requirements of the investigation described. By the special control of nutrition the experimental barley plants yielded tissues with a great capacity for salt uptake, apparently much greater than that possessed by the wheat plants used by Lundegårdh.

(5) Neither respiration nor salt uptake occurs uniformly throughout the root system. In calculating an arithmetical relation between respiration and anion absorption Lundegårdh takes no cognizance of this fact, nor of the complications caused by interaction of root and shoot.

(6) Lundegårdh's references to bio-electric phenomena do not elucidate the problem. The surfaces involved were not precisely defined and in any event the origin of such bio-electrical potentials is still controversial.

We may now note those parts of Prof. Lundegårdh's second article which refer to these points.

Lundegårdh states that we did not find the quantitative relations demanded by the concept of anion respiration because:

(a) The choice of treatments was too restricted.

(b) The process of salt uptake must be studied in an "organ exclusively designed to effect this process" and therefore experiments on cells of storage roots and stems are not admissible.

(c) The work of Hoagland and associates on excised roots is subject to the assumed complication that salts absorbed may exude from the single cut surface back into the external solution, so that the amount in the tissue is not a correct measure of that which is absorbed.

We are unable to accept these arguments. To restrict experimental attack on problems of salt uptake to any particular organ, for example, roots of grasses, is an unjustifiable and arbitrary conception. Salt uptake is one of the most general properties of living cells during their growth, and general conclusions must embrace the results of experiments on a wide range of cells and tissues. Our views were based on experiments on roots of barley and potato, a variety of storage roots, stems and modified leaves, growing leaves of dicotyledons and monocotyledons, as well as submerged aquatics and green algæ. While the most intensive investigations have demanded a restricted choice of materials. the general picture we have presented embraces work with all.

Lundegårdh implies that in storage tissues the anion absorption is too small to reveal the anion respiration effect. However, we clearly stated that in experiments that cover a wide range of salts and salt concentrations the *entire metabolism* of the tissue (not merely respiration) responded to the salt treatment. The ion absorption *was* large enough to produce marked effects, which are different in *kind* from those described by Lundegårdh.

Lundegårdh cites no proof that submerged, excised roots continue to exude salt. In any event, Hoagland and Broyer have made numerous studies on exudates of barley roots and find that the salt present in such exudates during the brief duration of the experiments is equivalent only to a very small fraction of the total salt absorbed by an active ("low-salt, high-sugar") root system. Comparisons have also been made between the salt removed from solution by intact plants and by submerged, excised, root systems. With plants having a high capacity for salt absorption, and for the short periods of the experiments, the excised roots and corresponding entire plants absorbed salt in quantities of similar magnitude. The ion uptake, for example, of potassium and easily absorbed anions was very large, and so far as we can find a basis for comparison, was more rapid than that reported by Lundegårdh or, indeed, by any other investigators of salt absorption in plants. As in the case of the storage tissues, we are certain that the roots absorbed salt in amounts and at rates such as to produce striking metabolic effects, although certain aspects of metabolism may be more prominent in one tissue than in the other.

We have not found anything in Lundegårdh's rejoinder to warrant discarding our view that the implications for the problem of salt uptake of bioelectric measurements are still obscure—we only wish it were otherwise. Amongst those who favour this line of work there cannot be said to be agreement concerning the nature or origin of the phenomena they investigate. Lundegårdh's re-statement still does not convey to us a clear picture of the boundaries which he regards as the seat of the phenomena he measures ; that is, whether this membrane is one of cells, for example, piliferous layer (epidermis of Lundegårdh), root cortex, or endodermis separating an external and internal intercellular fluid, or is a protoplasmic boundary membrane, across which the phenomena of ion accumulation in cells actually occur. Such phrases as "root tip" relative to electrode measurements require much more precise definition before they convey any anatomical meaning.

To return to the constant '*k*' of anion respiration. It is said to be "fairly constant" for an anion present only as a given salt (although in the experiments with barley roots this function would not be constant even with this restriction). With different cations the value of '*k*' is now said to "change somewhat", and it varies also with the ratio of absorbed anions to cations. So versatile a "constant" seems to us to lack utility.

Our purpose in this and our former communication is to suggest to the general reader the complexity of the problem of salt absorption by living cells, and also that the theory of Prof. Lundegårdh has not yet been established and generally accepted by plant physiologists. With regard to the quoted work of van Eijk on the salt marsh composite *Aster tripolium*, we note that it is rather the principle of a salt effect on respiration which van Eijk confirms (with which we are not in disagreement) and not the reality of the special anion effect, which even by van Eijk seems to be regarded as an open question. Van Eijk's values for the quantity "K" do not show that this has a constant value specific for each anion.

Finality cannot be obtained by further exchange of views in the columns of NATURE. Although we hope that the present discussion may serve a useful purpose, its continuance in this journal could not be justified.

STATISTICS AND ENGINEERING PRACTICE

DR. B. P. DUDDING and W. J. Jennett, of the G.E.C. Research Laboratories at Wembley, have contributed a paper on "Statistics" to the Institution of Electrical Engineers which was published on January 5 and should prove useful in engineering applications. Although there was no spoken discussion, the authors have made some minor changes so that it can be read as a contribution to a general written discussion which will be concluded not later than February 5.

The theory of statistics as a distinct branch of science did not begin to flourish until the last quarter of the nineteenth century ; in England, the work of Galton and Karl Pearson laid the foundations of the applications of the theory to many fields of science. Research workers in biological sciences and in agricultural industry were the first to turn these more recent advances to practical use. Great interest was stimulated by a series of lectures given by Dr. Shewhart at University College, London, in 1932. Later, the British Standards Institution formed a committee charged with the following terms of reference :

(1) To report on the application and use of statistical methods in standardization and specification of quality ; (2) to draw up a short report which would serve to awaken interest in the application of statistical methods on the part of manufacturers and others concerned with problems of standardization and specification ; (3) to consider what encouragement is necessary for the development of research on improved statistical methods and their application to industry ; and (4) to consider what steps should be taken to provide for co-operation with bodies in the United States of America and elsewhere instituted for similar objects.

Out of this activity also grew the formation of the Industrial and Agricultural Research Section of the Royal Statistical Society. The meetings of this Section have provided opportunities for technicians employed in industry to meet statisticians and for statisticians to meet and discuss with technical people the difficulties which arise in trying to apply statistical methods to the examination of industrial data. Many institutions have been interested in this development. At the present time, there are few industrial products which are not expected to conform with some standard of quality. Measures are taken to ensure that finished products will conform with quality standards demanded by consumers.

The main object of Messrs. Dudding and Jennett was to emphasize the essential statistical nature of many technical problems and the part that chance plays in many technical decisions, and to demonstrate the need for a technique which will give assistance in making deductions from test data.

The following technical improvements and economies accrue to those industrialists who cultivate the statistical outlook and apply statistical methods to the scrutiny of their data. The errors of judgment arising from ambiguities due to the effect of chance, which lead to incorrect action, are reduced. Development work involving reasonably large-scale production can be planned most economically and the results rightly appraised. The efficiencies of the specifications used can be improved, and simple and efficient systematic methods of presenting data requiring daily scrutiny can be readily devised.

The authors explain fully the academic method of considering the frequency distribution of observations by the Gaussian curve, and the use of mean and standard deviations is explained. The importance of the methods given for carrying out specifications which involve sampling is clearly stated.

Numerical examples are included which will help those beginning the study of variance. An example has been given where an experienced engineer lacking statistical knowledge, and the statistician lacking practical knowledge, would probably have come to the same erroneous conclusion. Correct diagnosis of the difficulty in the factory was only possible by a combination of the attributes of the two.

SEVENTY YEARS AGO

NATURE, vol. 1, January 20, 1870

Kant's Views on Space

PROF. T. H. HUXLEY concludes a letter on this subject with . . . "there can be no doubt that that thorough and acute student of Kant, Dr. Ingleby, was perfectly right when he said that Kant would have repudiated the affirmation that 'space is a form of thought'. For in these sentences [quoted from Kant's writings], and in many others which might be cited, Kant expressly lays down the doctrine that thought is the work of understanding, intuition of the sense ; and that space, like time, is an intuition. The only 'forms of thought', in Kant's sense, are the categories."

Projected Channel Railways

THE second of a series of three articles on this topic was published. The first article discussed the cultural advantages for Great Britain of closer connexion with the continent of Europe, and proceeded to demolish a fantastic scheme for a railway bridge across the English Channel. The second article dealt with a proposed Channel Tunnel and included a map of the route from the engineers' report issued by the promoters. "We are of opinion that it is not an unreasonable proposition, to drive a tunnel under the Channel, but that in some measure it must be a venture. If we are to undertake such a venture to gain a magnificent prize, of immense value to the English and French nations, we must be prepared to meet all ordinary eventualities. . . . The first step towards accomplishing the object would be to obtain a geological section across the Channel . . . from actual test of the materials which compose the bed of the Channel."

Meteorological Blockade

SIR WILLIAM THOMSON, F.R.S. [afterwards Lord Kelvin] discusses Dr. Balfour Stewart's proposal for a cordon of meteorological stations around a district to keep an exact account of the quantity of water vapour entering and leaving the space over the district in question. "This appears to me a most valuable proposal, which, if well carried out, must have a very important influence, tending to raise meteorology from its present empirical condition to the rank of a science . . . the same system of account-keeping ought to be applied to electricity . . . among the many unknown quantities involved, the two departments of the blockade combined will give means for eliminating some and estimating others."

WE notice that an individual was examined on Tuesday at Worship Street on the charge of sweating sovereigns. The details of the case, which are of considerable importance to the public, will be watched with interest. It appears that the coins are dissolved by acid, aided by a battery, and that the loss in some cases equals about two shillings in the sovereign.

IT was announced by Mr. Lockyer at the meeting of the Royal Astronomical Society on Friday last, that the great refractor of 25 inches aperture, constructed by the Messrs. Cooke, of York, is so near completion that it will be erected in the observatory prepared for it at Gateshead early next month.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned :

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING AND PHYSICS at the Technical College, Coventry—The Director of Education, Council House, Coventry (January 26).

HEADMASTER for the Pentre Junior Technical School—The Director of Education, Council Offices, Pentre, Rhondda (January 27).

TEMPORARY INSTRUCTOR LIEUTENANTS in the Royal Navy—The Director, Education Department, Admiralty, Whitehall, S.W.1 (January 31).

GRADUATE ASSISTANT to teach ENGINEERING Subjects, PHYSICS and MATHEMATICS—The Principal, Hendon Technical Institute, The Burroughs, N.W.4 (January 31).

ENGINEERING WORKSHOPS INSTRUCTOR to take Engineering Drawing and Allied Subjects (Elementary Mathematics and Mechanics)—The Principal, Hendon Technical Institute, The Burroughs, N.W.4 (January 31).

LECTURER (Grade II) IN DENTAL PROSTHESIS—The Secretary and Registrar, University, Bristol (February 10).

DIRECTOR OF RESEARCH of the Linen Industry Research Association—The Secretary, The Research Institute, Lambeg, Co. Antrim (March 1).

JUNIOR ASSISTANT CHEMISTS—The Secretary, Linen Industry Research Institute, Lambeg, Co. Antrim.

ENGINEER for the Public Works Department of the Government of Hong Kong—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9006).

SCIENCE AND EDUCATIONAL POLICY

THE statement of the Prime Minister that the aims of Great Britain during the present struggle must be sharply differentiated into war aims and peace aims amounted to much more than a reply to the demands for a clarification of what is to be our attitude when the War comes to an end. It is essential, however, that the wider peace aims should be constantly reiterated in order that they may remain fixed before our eyes. It would be more than regrettable if the ideals of freedom, liberty and equality that have led the Allies to take up arms were lost sight of even temporarily in our efforts to defeat the enemy. Mr. J. B. Priestley, in speaking of the drama, said recently that a momentary blurring of the objects for which we are fighting would be enough to invalidate our reasons for having gone to war.

A real and immediate problem which deserves consideration is whether a long-term national policy of scientific education ought not to be introduced into the schools of Great Britain. It is becoming more and more apparent that the provision of scientific education is far from being scientifically planned, a matter which could be adjusted by closer co-operation between scientists and educationists. Here the different forms of educational institutions would have to be considered not separately but as components of a system which aims at the development of beings whose lives are continuous processes. In this respect the insistent demand raised in the report of King George's Jubilee Trust* for continuation classes for all up to the age of eighteen should receive adequate consideration. The Industrial Revolution, the growth of the physical sciences, the mechanization of ways of living with its consequences in transport, communication and manufacture have all combined to produce an environment in which educational equipment in many cases leaves the ordinary citizen thwarted and helpless. The ideal of science is the pursuit of objective truth ; if material progress is to continue, it is essential to keep this ideal clearly in view in the prosecution of measures whereby scientific truths might be made to contribute to human welfare.

Reflection on the standard of living of masses of the population makes one painfully aware that the applications of well-established scientific truths are not being carried out in an efficient and objective fashion. There is no need to emphasize the fact that science must look for a policy which will in no respect imitate the nationalistic efforts of countries where scientific truths are distorted to conform to ideological needs. Various factors indicate that the population of Great Britain is likely to decrease during the next few years. If, as compensation, the quality of the people is to be improved, scientific workers, and especially those in the biological field, should decide the paths upon which the course of science development is to be guided.

Co-operation between scientific workers and educationists led to marked improvement in living standards of the nation while we were at peace. In these times of stress and anxiety, the value of the wider extension of scientific methods of thought and practice is apparent. The national effort will only reach its maximum when due regard is paid to the health of the nation as a whole. In this connexion, it is doubtful whether scientific workers are being allowed to play a sufficiently active part in the various schemes of food production and control. Much could be done, especially in the reception areas, by the introduction of classes for teachers and youth leaders, where the specific problems bound up with evacuation could be discussed. The Workers' Educational Association, the Townswomen's Guilds and other bodies have already sponsored classes of this type. These could be usefully extended. The rural community councils and women's institutes provide means whereby scientific practice could be more quickly transferred to non-urban communities.

---

* "The Needs of Youth". By A. E. Morgan. (London : Oxford University Press, 1939.)

One aspect of this policy would be the need for greater and more effective co-operation between scientists and educationists in deciding upon the content of the general school curriculum, and in particular the science part itself. The Science Masters' Association has approached the problem in the right manner by taking steps to revise examination syllabuses in liaison with university staffs; this has resulted in the publication of reports on various subjects, including the recent one on the teaching of general science. But their scope of action is necessarily limited, and the origins of the present conflict indicate the necessity for a re-orientation of the school science content if the ideals expressed in the Spens Report are to be given effect. The Consultative Committee responsible for this report has in no wise exaggerated the case when it states that even the possibilities of science teaching have not yet been fully apprehended.

One of the more urgent problems that calls for investigation is the need for a clearer definition of the concept of social biology as an educational medium. Another avenue that could be explored with profit by scientists and educationists is the present rating of science in many school syllabuses. Apart from its use in technical and vocational training, science as an educational subject often receives poor recognition. In the Common Entrance Examination to Public Schools, for example, Latin still remains as the symbol of what is to be desired in the shape of compulsory attainment, while science is relegated to a minor, optional position. This specific instance is but a general symptom of a condition which is more widespread than is obvious on superficial examination. Such an assessment often fails to accord both science and industry their true social worth, while much useful talent is frequently diverted elsewhere. Further, in many schools science is considered to play little or no part in the process of character training; such restrictions lead to numerous psychological problems, centred upon the true worth of science, which have no real foundation. If some of these difficulties are to be adjusted, considerable effort will have to be exerted by scientific workers with an interest and enthusiasm that is based upon inflexible moral purpose and a real concern for human progress.

The difficulties encountered in the development of the Colonial Empire merit special attention. Until very recently the significance of the tropical and sub-tropical Dependencies has been viewed as through a glass, darkly. It is a tribute to our administrators that, despite this lack of interest in Great Britain, in at least some parts of the Empire it is more than probable that education is being approached in a spirit that approximates more nearly to being truly scientific than is the case nearer home. In some places excellent results are being obtained, and the part played by educationists in the establishment of stability in these rapidly evolving Colonies demands the widest recognition. The recent extension of the college for native African students at Makerere in Uganda is a new milestone in colonial development. In the Colonies, greater interest shown by scientific workers would produce even more striking results.

It has yet to be decided whether positions of importance in the Colonies should be allocated to men and women who have specialized only in one or two branches of science. Evidence comes to hand constantly to show that, whereas specialists are essential for university teaching and research posts, for general educational purposes the Colonies need people with a wider scientific training, preferably with a biological bias; it may be added that there is a body of opinion in Great Britain which maintains that this is also applicable to home conditions. For the Colonies, undoubtedly, greater attention should be paid to the recruitment of those whose task it will be both to undertake teaching duties themselves and to train and inspect native teachers in the Colonial Empire.

The planning of programmes for the present year is more than hazardous at this time, but, because of the rich opportunities which are presented, it is to be desired that responsible authorities will make at least tentative preparations for the holding of 'refresher' courses and vacation schools wherever this is possible. In general, 'refresher' courses in science have either been concerned with imparting pure academic or technical knowledge, or have served their purpose in spreading scientific knowledge and principles to a wider audience. The latter would probably be the more fruitful course to be adopted while we are at war. Opportunities might be provided during the approaching summer for teachers, club leaders and other youth workers to be able to make refreshing contacts with members of their own professions, and to obtain valuable help and guidance from leading scientific workers and educationists. For various reasons, it seems unlikely that the Board of Education will be able to proceed with its admirable courses in science during the summer, so that the opportunities provided by other organizations would be of inestimable value.

MEMORIES OF A PALÆONTOLOGIST

Some Memories of a Palæontologist
By William Berryman Scott. Pp. vi+336. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1939.) 17*s*. 6*d*. net.

DURING the past sixty years, American palæontologists have taken a very large share in adding to our knowledge of fossil mammals. They have not only made remarkable discoveries on their own continent, but have also worked in close association with their colleagues in other countries.

Among them during the whole of this long period, Prof. William B. Scott, of Princeton University, has been especially active, and few have ranged over a wider field. Since 1877, when he made his first collecting expedition to the West with his classmate, Henry Fairfield Osborn, until the present day, when he has joined Prof. Glen L. Jepsen in preparing a large memoir on the Oligocene mammals from South Dakota, he has travelled and engaged in research with tireless energy. His experiences therefore have been many and varied, and while occupied with his own technical problems he has seen much of the world in general. He has now recorded some of his memories in an attractive volume which will be welcomed by all who are interested in the ways of life of scientific men.

Prof. Scott, through his mother, is a great-great-great-grandson of Benjamin Franklin, and he began life at Princeton in unusually intellectual surroundings. From the beginning his inclinations were towards natural science, and when he was a schoolboy his interest in geology was first roused by his grandfather who made some casual remarks to him about the nature of coal. At Princeton he studied under Prof. Arnold Guyot, whom he eventually succeeded in the professorship of geology. In London he attended Prof. Huxley's course in comparative anatomy; at Cambridge he studied embryology with Francis M. Balfour; and at Heidelberg he spent much time in research under the direction of Carl Gegenbaur. He was thus well equipped for both geological and biological work, and he gives many interesting reminiscences of his teachers and distinguished fellow students. His visits to Europe also brought him into contact with other leaders in geological and biological science of whom he records impressions. His experiences of England and Germany seem to have been particularly happy.

Prof. Scott has much to say of life in Princeton, where he witnessed the growth of the old College into the University. He describes his expeditions to the West to collect fossils, beginning in the days when the Indians were still troublesome; and he makes many references to the rivalry of Cope and Marsh, who were his predecessors in the field. There are also observations on South Africa, which he visited with the British Association in 1905; on Panama, which he visited in 1911; and on Spain, where he attended the International Geological Congress in 1926.

Prof. Scott's most important work outside North America was his organization of the Princeton University Expedition to Patagonia under Hatcher and Peterson during 1896–99. Between 1901 and 1931 he edited the series of handsome volumes which record the results, and he himself contributed most of the descriptions of the fossil mammals. In 1901 he visited the Argentine so that he might study and photograph the fragments of similar fossil mammals in La Plata which had already been described by Ameghino and others. Reminiscences of this journey occupy an interesting chapter.

During the past few years Prof. Scott has not only continued the researches on Oligocene mammals already mentioned, but has also published new editions of his well-known "Introduction to Geology" and "History of Land Mammals in the Western Hemisphere". He has rewritten the greater part of the latter book and made it an indispensable up-to-date work of reference. Now that he is an octogenarian, he adds to our indebtedness by giving us a stimulating collection of memories, which show how wide may be the outside interests of one who devotes himself to palæontology. ARTHUR SMITH WOODWARD.

PLANT VIRUS DIESEASES

Plant Viruses and Virus Diseases
By F. C. Bawden. (A New Series of Plant Science Books, Vol. 5.) Pp. xii+272. (Leiden: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1939.) 7 guilders.

THE earlier investigations of virus diseases of plants were attempted by the standard methods of the plant pathologists, and failed to reveal the cause of the disease, or to elucidate the nature of the infective agents. These methods have been supplemented by a technique of the widest biological basis, including that used by biochemists and physicists to investigate proteins and other compounds of high molecular weight. The author, with his colleagues, has played a prominent part in the isolation, purification and chemical recognition of nucleoproteins obtained only from infected plants. His hypothesis, freely accepted to-day, considers the nucleoproteins to be the viruses; this forms the theme of his book, which might with advantage have been entitled "Recent Research on the Nature of Plant Viruses". Thus it differs, particularly in outlook but also in treatment, from other recent text-books of virus diseases which are primarily concerned with the economic host plants; this one especially considers the infective agents.

In the introductory pages the author criticizes with acumen suggested schemes of classification or nomenclature based largely on records of host plants infected; in later chapters a classification based on the actions and properties of the viruses is put forward. Such a desirable change can only take place when sufficient knowledge of the viruses is gained; whereas little benefit and considerable confusion may arise from reshuffling an artificial system of nomenclature, the earlier classifications were based on the limited available facts chiefly concerned with the host plants.

Botanical readers, some perhaps less familiar with serological technique, will find these methods described as they are now utilized in virus research. Evidence shows that the viruses are themselves the antigens; for the purer the virus preparation the more active it has proved, and further, a common antigen may be obtained, for example, from plants of tobacco and phlox, infected with the virus causing tobacco mosaic. Crystalline nucleoproteins have given results of the same order, and are now regarded as the antigens specific to virus-infected plants. This is part of the experimental foundation of the author's hypothesis. Serological technique has also proved of value in identification of the viruses and can be used to distinguish strains of the same virus.

Since Stanley (1935) claimed to have isolated the tobacco mosaic virus, much progress has been made in the methods of purification, and the text shows those employed to obtain samples of tobacco mosaic, potato 'X', tomato bushy stunt, and tobacco necrosis viruses. One yield of 80 per cent of the total protein content of the sap expressed from frozen leaves has been claimed to be virus; but in other cases cited, 2 gm. per litre of cell sap are considered to be virus. From healthy plants no such compounds are obtained by similar procedure.

Later chapters deal with the composition of viruses as revealed by chemical analysis—where the phosphorus and carbohydrate derived from the nucleic acid are of vital importance as without such fractions activity is greatly reduced—and with their optical and other physical properties, including crystalline structure studied by X-rays. Estimates of the size of the particles and their molecular weight are included. A brief account is given of the limited work that has been carried out on the physiology of virus-infected plants. The author reviews possible control measures and considers the breeding of resistant varieties to be a slow but promising line of work. Protection afforded by chance or deliberate infection with mild strains, valuable as it is with certain crops, is not considered likely to be of general use; it appears impracticable to 'vaccinate' plants against more than one virus because of the interactions and complications that may ensue.

In the concluding pages attention is focused upon the question so frequently asked by the earlier investigators: Are viruses living organisms? A straightforward definite answer cannot be given. Further knowledge regarding the activities of viruses in living tissues is needed. In the meantime it is necessary to re-examine carefully the criteria applicable to this judgment in the light of the information already known about viruses.

The book forms a readable account of recent brilliant research, the facts are authentically presented, and the literature adequately surveyed. Here and there a few trivial errors in the type have escaped the proof reader's attention; there are several short reiterations in the introductory paragraphs to the chapters. Biologists are deeply indebted to Mr. Bawden for his critical survey of the progress so recently made in this field of research.

YOUTH ON THE PROW IN CHEMISTRY

Young Chemists and Great Discoveries
By Prof. James Kendall. Pp. xvi + 272 + 23 plates. (London: G. Bell and Sons, Ltd., 1939.) 7*s*. 6*d*. net.

IN this book of the Royal Institution Christmas Lectures of 1938–39, Prof. Kendall records how "the youthful breast, inspir'd by truth's bright ray", arrived at some of the most spectacular discoveries in the history of chemistry. Following Ostwald, he divides his youthful paladins into two classes: the romantic and the classical, exemplified by Davy and Faraday. As one would have anticipated, his first lecture was devoted to the romantic Humphry Davy, an ideal subject for such a theme, such an audience, and such a place. Then followed naturally that wonderful example of the age-old story of the master and the apprentice provided by the interwoven careers and contrasting personalities of Davy and Faraday.

Davy carried out his dramatic experiments on the inhalation of nitrous oxide at the age of twenty; at twenty-two he took London by storm through his brilliant lectures at the Royal Institution; at twenty-four he was elected to the Royal Society; at twenty-eight he discovered potassium. Here, then, is a perfect example of the youthful genius in chemistry.

However, like van 't Hoff, who also leaped to fame at the age of twenty-two, Davy had burnt himself out at fifty. Indeed, from Prof. Kendall's examples it seems that if the romantic type be symbolized by Davy's flaming globule of potassium, the classical type may be likened to the candle, about which Faraday lectured so aptly and charmingly to his juvenile auditory at the Royal Institution. Faraday's first important discovery was made when he was about thirty, and the flame of his genius shone clear and steady until he entered into the twilight of a long and fruitful life.

Prof. Kendall's story, always interesting and animated, ranges from Davy and Faraday through Perkin, Couper and Kekulé, Pasteur and van 't Hoff, Arrhenius and the Braggs, Newlands and Mendeléeff, Bohr and Moseley, to the "first young heroine", Madame Curie, and ends across the Atlantic with Robert Hare, Charles Martin Hall and Irving Langmuir (who characteristically took his seat in a row labelled 'Juveniles Only' at Prof. Kendall's first lecture). The narrative thus traverses an extensive field, and Prof. Kendall's clear and easy style enables him to introduce his readers, as he introduced his juvenile auditory, to such complexities as structural formulæ, polarized light, asymmetric molecules, ionization, the classification of the elements, isotopes and radioactivity.

It is difficult to discover flaws in this entertaining story, although on one or two occasions it may be felt that Prof. Kendall shows a little indulgence to his young heroes. Thus, in defending Davy against those who have accused him of vanity and snobbery, Prof. Kendall quotes Dalton's statement: "The principal failing in his character is that he does not smoke." This testimonial to Davy's character becomes less impressive, however, when one refers to Dalton's original letter, which reads: "The principal failing in his character as a philosopher is that he does not smoke." Moreover, it is scarcely fair to one who has been called "the Scotch Faraday" to say that "only the mighty Faraday roused Liebig's admiration" among the chemists he met in England in 1837; for at that time, as Tilden has remarked, "Faraday having long abandoned the pursuit of pure chemistry, the most famous by far among English [that is, British] chemists was Thomas Graham", who certainly won Liebig's high approbation. "I had a very long and agreeable letter from Liebig a few days ago," wrote Graham to his sister Margaret on November 24, 1837, "conveying the information that his University have made me a Dr. of Philosophy *causâ honoris*. . . . He has a grand project of publishing a chemical journal in three languages, to be edited by Liebig, Dumas, and myself."

As Prof. Kendall points out, several famous chemists have been poets, and the youthful Davy was also the subject of anonymous sonnets from fair admirers. We suspect that if Prof. Kendall had not been an eminent chemist he would have achieved fame as a dramatist, if not indeed as an interpreter of the drama. His lectures were rich in dramatic moments and quick changes. His book, too, ends on a dramatic note. As we are about to lay it down we discover that the "young chemist" whose classical features adorn the dust jacket is not Davy as we have hitherto supposed. To our surprise this charming illustration proves to be an early portrait of Albert Edward, Prince of Wales, afterwards King Edward VII, who in his youth received instruction in chemistry from Lyon Playfair at Edinburgh and took part there in the dramatic experiment with boiling lead which is described at the close of Prof. Kendall's book : "the lecturer and his two gallant volunteers in turn passed their hands to and fro through the stream [of white-hot lead], and the final experiment of the 113th course of Christmas Lectures adapted to a juvenile auditory to be given at the Royal Institution was carried to a successful conclusion".

This absorbing account of youthful achievement in the realm of chemistry cannot fail to arouse and hold the interest of readers of all ages. The volume is attractively produced and copiously illustrated with plates and figures. It contains references to many of the experiments and exhibits of the original lectures, and each chapter is provided with a useful bibliography. The book gives rise to sundry interesting reflections. What was the spark causing the tinder of each youthful genius to burst into flame ? Is there still scope in science for the youthful pioneer, in these days of intense specialization and team work ? Would Faraday, with his meagre formal education and elementary knowledge of arithmetic, have been able in this exacting age to break his birth's invidious bar ? These are some of the intriguing questions to which the intelligent reader must supply his own answers. JOHN READ.

GENETICS OF COTTON

The Genetics of Cotton
By Dr. Sydney Cross Harland. Pp. 193. (London : Jonathan Cape, Ltd., 1939.) 10*s*. 6*d*. net.

THE great economic importance of the world's cotton crop has led to marked advances in the genetics of cotton since 1924, when the most valuable New World species of cultivated cotton were found to be tetraploid. The researches of Dr. Harland have occupied a leading place in this development, and the present book is a fitting summary of knowledge regarding the genetics and cytology of the genus Gossypium.

The first chapter, which is devoted to the taxonomy of the group, recognizes eighteen species, while ten others recognized by some authors are reduced to variety rank and two are assigned to other genera. In addition, *Gossypium Robinsonii*, of Western Australia, is insufficiently known and recent efforts to find it in the wild condition have been unsuccessful. Numerous specific names of cottons in the West Indies and South America are regarded as local races of *barbadense* or *purpurascens*.

The fact that four American and three Polynesian species are tetraploids with 52 chromosomes is of fundamental importance for the genetics of the cultivated cottons. The existence of five wild American diploid species, as well as other diploid species in Africa, Asia, and Australia, shows not only the great age of the genus (regarded as Cretaceous in origin) but also serves as the basis for various views regarding the origin and history of the valuable American tetraploids (Sea Island, Upland, etc.). It is evident that these form a younger section of the genus, having been derived, probably as allotetraploids, from diploid ancestors.

The cytological chapter presents the available evidence from chromosome morphology as well as number, and particularly from chromosome pairing in F_1 interspecific hybrids. Supposed constant differences in chromosome size between the Old and New World species have led to the view that the American tetraploids have resulted from chromosome doubling in sterile hybrids between species from these respective original sources. The chromosome sizes in these presumed amphidiploids do not apparently support this view, and Upcott's reinvestigation of the case of *Æsculus carnea* does not show (as is stated on p. 44) that this amphidiploid has 40 large chromosomes derived from one parent and 40 small ones from the other. Nevertheless, although the evidence of chromosome size gives little support to the view that the American tetraploid species came from crosses between Asiatic and American diploids, yet the pairing in F_1 hybrids does support such a conclusion, for certain crosses between Asiatic species and New World tetraploids give thirteen pairs and thirteen single chromosomes. The evidence is not final, but the existence of tetraploids in Polynesia suggests that this condition goes back a long way in the history of the cottons.

The bulk of Dr. Harland's book is naturally devoted to the numerous results of breeding experiments. Several series of multiple allelomorphs are known, some members of which belong to different species, as in red pigmentation, leaf shape and seed fuzz. Several cases of linkage groups have been found, but with the large number of chromosomes it will be a long time before adequate chromosome maps can be constructed.

This book will be indispensable to all those concerned in cotton breeding, and to geneticists, especially for the work on interspecific modifying genes in a group of species the age of which can only be measured in geological time.

R. RUGGLES GATES.

SOME BIOLOGICAL APPLICATIONS OF NEUTRONS AND ARTIFICIAL RADIOACTIVITY*

By Dr. John H. Lawrence,

Radiation Laboratory, University of California, Berkeley

THE biological and medical sciences are being stimulated and benefited by the recent discoveries of the nuclear physicist in a manner similar to that following the discovery of the naturally occurring radioactive elements and the production of X-rays. The nuclear physicist can now induce radioactivity in practically all of the elements, and he can harness a beam of neutrons of intense biological activity. This new wonderland for the biologist has been brought about by such events as the first successful experiments of Joliot and Curie in artificial radioactivity, the discovery of the neutron by Chadwick, the discovery of heavy hydrogen by Urey, and the development of the cyclotron by E. O. Lawrence and his associates.

During the past four years, workers at the University of California have been intensely interested in the biological applications of these products of the physicist, and recently a new medical-biological laboratory dedicated to this study and housing the new 220-ton cyclotron—the William H. Crocker Radiation Laboratory—has been completed in Berkeley. Because of its ability to produce large quantities of the various radio-elements and neutron rays, the cyclotron is the nucleus of this unit. The Laboratory is, however, staffed not only by physicists, but also by chemists, biologists, cytologists, bacteriologists, physicians and radiologists—all of whom are interested in both the fundamental and practical problems concerned with the interaction of radiation and matter. My purpose here is to discuss briefly some of the investigations carried on in this laboratory or in conjunction with it. Unfortunately, there is not sufficient space to discuss the extensive and important work being done in this field in other laboratories.

When Hevesy first used radium D, an isotope of lead, as a 'tracer' of lead movement in plants, the potential value of similar isotopes of elements which are important in physiological processes, such as phosphorus, sodium, iron and iodine, became apparent. These and other radioactive isotopes are now available; and, since they are chemically like their inactive relatives, their radiations simply label or tag them and enable the investigator (with the aid of a Geiger counter) to study their average exchange and distribution in biological and chemical processes, in health and disease. The effect of irradiation on the reaction is avoided by the use of sufficiently small 'tracer' amounts. On the other hand, many of these isotopes may be used as potent sources of radiation if the metabolism of the element in question is not being studied. In Table 1 are listed some of the isotopes that are used in this University. A brief discussion of studies in which these isotopes are employed follows.

Table 1.

Atomic number	Radio-element	Radiation	Half-life
1	Hydrogen (3)	Beta	150–170 days
6	Carbon (11)	Positron and gamma	20·5 minutes
11	Sodium (24)	Beta and gamma	14·8 hours
15	Phosphorus(32)	Beta	14·3 days
16	Sulphur (35)	Beta	88 days
17	Chlorine (34)	Positron and gamma	33 minutes
19	Potassium (42)	Beta and gamma	12·4 hours
20	Calcium (45)	Beta and gamma	180 days
26	Iron (59)	Beta and gamma	47 days

Radioactive hydrogen is written ${}_1H^3$, in contrast to ordinary hydrogen (${}_1H^1$) and heavy hydrogen (${}_1H^2$), and has only recently been discovered by Alvarez and Cornog of this Laboratory. This newly labelled form is used in biological work and promises to become a valuable adjunct to heavy hydrogen, which has been so extensively used in 'tracer' studies. Although radio-carbon has a very short half-life (20·5 minutes), Ruben, Hassid and Kamen are successfully using it in the study of photosynthesis. Leaves of barley plants grown in an atmosphere of C^*O_2 form radioactive carbohydrates†, even when the plants are kept in darkness prior to exposure to C^*O_2. The bulk of the radioactive material found in the plant is water-soluble and does not contain carbohydrate, carbonate, keto acids or pigments. Jenny and Overstreet of the College of Agriculture grew barley in the presence of K* and showed that the intake of ions is not a uni-directional process, but that ions of the same species may move into the root and out of the root at the same time. Stout and Hoagland of the same department, using the radioactive isotopes of potassium, sodium, phosphorus, and bromine, studied their upward movement after absorption by the roots in actively growing willow and geranium plants. They found that when salts are absorbed by roots, some portion enters the xylem within very short periods of time, and is carried rapidly towards the leaves under the influence of transpiration. That the content of radioactivity in the bark as compared with the root is slight indicates that movement of salts in the former is very slow.

---

*Based in part on a paper given before Section A (Mathematical and Physical Sciences) of the British Association, given on August 31 and September 1, 1939, at Dundee.

†The radioactive form of an element is denoted by an asterisk.

Mullins, of the Department of Zoology, has investigated the effect of increasing activities of radio-sodium on the penetration of Na^+ into the single-celled alga Nitella. His results show that, below certain activity concentrations, there is no 'radiation' effect, and point out the importance of using low activities in 'tracer' work. Hamilton is making an extensive study of the physiology of the isotopes of sodium, potassium, iodine and other elements, in health and disease. Their rapid absorption and distribution is evidenced by their appearance in the hand a few minutes after oral administration of small amounts. The isotope of iodine is proving to be valuable in the study of thyroid physiology. Hamilton has demonstrated the marked concentration of ingested iodine in the thyroid gland and has been able to photograph the distribution of iodine by placing the excised gland on a photographic film. Anderson and her associates of the Institute of Experimental Biology have found that in adrenalectomized rats a single dose of 'tagged' sodium is rapidly lost, while potassium tends to be retained.

Radio-phosphorus (P^{32}) has been the most extensively used radioactive isotope. The ease of manufacture in the cyclotron and its relatively

Standing by the corner of the magnet and adjusting the helium flow to the target chamber is the late Dr. Harold Walke, of the University of Liverpool. On the table in the foreground is an experimental deuterium generator. The target chamber is behind, marked by the two port holes. Above and to the rear is seen the aluminium oscillator house or radio-frequency power supply. Photograph taken by Dr. Donald Cooksey, assistant director of the Radiation Laboratory.

long half-life (14·3 days) make it ideal for biological studies. Chaikoff and his associates in their studies of phospholipid metabolism have shown that various kinds of neoplasms in animals have individual rates of phospholipid turnover, and that cell type does not seem to be the determining factor. In association with Scott and Tuttle, the metabolism of labelled phosphorus in leukæmia in both animals and man is being investigated. The finding that in leukæmic mice the phosphorus turnover is apparently proportional to the degree of leukæmic infiltration suggested the use of radiophosphorus as a source of radiation in the treatment of leukæmia in humans. The concentration of the radio-phosphorus in the areas infiltrated with leukæmic cells tends to localize the therapeutic irradiation (beta-rays). Given by mouth in the form of sodium phosphate, phosphorus is well absorbed (75 per cent) and slowly excreted (2 per cent per day). The turnover of phosphorus in red cells is rapid, whereas the white cells retain it for longer periods of time. Numerous patients suffering from chronic leukæmia are being treated with this material, and in many instances remissions in the disease are obtained.

Tarver and Schmidt, of the Department of Biochemistry, have synthesized methionine from radio-sulphur and, after feeding it to rats, have shown that the radio-sulphur may later appear as cystine extracted from the tissues. Finally, Whipple and his associates at the University of Rochester, in their studies on normal and anæmic dogs, report the following: radio-iron is poorly absorbed by normal animals; anæmic animals absorb iron in proportion to their need for it; plasma is the medium for the transport of iron; the rapid appearance of iron in the red blood cells is spectacular.

The intense beam of neutrons produced by the cyclotron has made it possible to investigate their biological effects on various objects such as bacteria, plants, Drosophila eggs, animal tumours and normal mammals. This new penetrating form of radiation has intense biological effects, even greater than X-rays or gamma rays, on normal and tumour tissue, but when compared with X-rays, selectively affects some tissues more than others. Experiments on animals indicating that neutrons are more destructive to neoplastic tissue than to normal tissue suggested their trial in cancer therapy. In association with R. S. Stone, of the Department of Roentgenology, patients suffering from cancer are now regularly being treated with neutrons from the new 60-inch medical cyclotron. The recent experiments of Kruger in this Laboratory have opened up another possible application of neutrons to cancer therapy. He has demonstrated that cancers from mice placed in non-toxic concentrations of boric acid and irradiated with slow neutrons can be killed with doses of irradiation harmless to tissues not in contact with boron. The slow neutron is captured by the boron nucleus. The combination emits two heavy ionizing particles in opposite directions—an alpha particle and a lithium nucleus—which traverse a distance of about 7 μ in tissue and thus approximate an explosion within the cell.

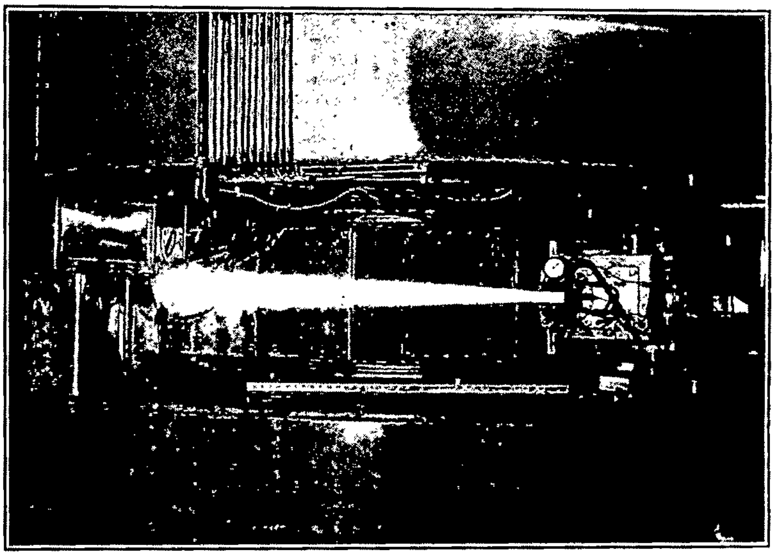

Fig. 2.

THE PATH OF A 16-MILLION ELECTRON VOLT DEUTERON BEAM TRAVERSING THE AIR FOR A DISTANCE OF NEARLY FIVE FEET.

These particles emerge from the vacuum of the target chamber with a velocity of approximately 18,000 miles per second. In slowing down over the course of their path, they give up their energy to the air molecules, causing them to glow with a violet light. However, in practice, a target to be made radioactive is placed at the emergent point of the beam and thus bombarded. Where neutrons are desired the target used is beryllium. Photograph taken by Dr. Donald Cooksey, assistant director of the Radiation Laboratory.

Although the great contribution of the new nuclear physics to the problems of biology and medicine is certainly the 'labelled' or 'tagged' isotope, nevertheless it seems important to pursue the possibilities of artificial radioactivity and neutron rays in cancer therapy until a more satisfactory answer to this problem has been reached.

MOUND EXPLORATION IN THE TENNESSEE VALLEY, U.S.A.

THE operations of the Tennessee Valley Authority in the United States of America, by the erection of dams to collect and control the waters of the Tennessee River and its affluents, will inundate to a considerable depth a vast tract of land, which to the archæologist and the student of the pre- and proto-history of the indigenous peoples of America is one of the most interesting regions of the continent north of the tropics. Unfortunately, in a cultural sense it is still incompletely understood. Though a great part of it, and curiously enough that especially suited to aboriginal pursuits and modes of life, was still unoccupied by surrounding tribes, possibly owing to mutual rivalries, when first visited by the white man in the sixteenth century, nevertheless the whole country abounds in evidence of prehistoric occupation in the form of mounds, shell heaps, stone implements, pottery, old fields, burial caves, and ancient cemeteries. From about 1660 onwards, these vacant lands were occupied successively by Shawnee, Chickasaw, Cherokee and Creeks, with a number of lesser tribes of uncertain affinities.

So early in the history of the Tennessee Valley Authority project as 1933, it was pointed out that the building of the dams and consequent flooding of large areas of the valley would destroy these records of prehistory for all time, unless some plan of conservation could be undertaken. Already the construction of the Wilson Dam, near Florence in Alabama, by the United States Government during the War of 1914–18, had created a lake 23 square miles in area; and to this inundation a further 100 square miles was now to be added. Accordingly, towards the close of 1933, a conference was held at Knoxville which was attended by representatives of the Authority and the Universities of Tennessee and Alabama, with Mr. Niel M. Judd of the Smithsonian Institution as consultant. As a result, archæological surveys of the areas affected were instituted and a number of excavations have been carried out with moneys provided out of Federal funds for the relief of unemployment, with the assistance of grants from universities and other learned bodies. Reports on the results of the survey work and excavation will, for the most part, be published when ready by the Smithsonian Institution of Washington.

Although the existence of a large number of mounds and other prehistoric remains in the great river-valley system, Ohio–Tennessee–Mississippi, of the United States has long been known and their character frequently described and discussed, it is only of recent years, thanks mainly to the work of Mr. Warren K. Moorhead and a small band of enthusiastic investigators, that anything approaching real understanding of the mound-culture has begun to emerge. At the moment, the focus of the problem is the distribution affinities and development of the 'Hopewell' culture, of which outstanding characters appear in what follows.

A more general characterization of the culture of these mounds, however, is given by T. M. N. Lewis, of the University of Tennessee, in a preliminary report to the American Philosophical Society on archæological investigations in the Tennessee Valley during the past five years, to the cost of which the Society had made grants from the Penrose Fund in aid of research[1].

A large quantity of documented archæological material and skeletal remains was obtained, from which the most interesting result to emerge, pending further and more detailed analysis, was the apparent linkage of the aboriginal peoples of Tennessee with those of Middle America. The large earthworks having the form of truncated pyramids, which have now been meticulously excavated, follow in cruder fashion the methods of construction of the temple pyramids of Central American lands, in which the ruins of temple buildings are found to surmount superimposed substructures. Here in Tennessee, however, the substructures are not stone-plated, as they are in the south, but are constructed of clay, whereas the superstructures, in which the religious ceremonies and business of government were carried on, were of poles, bark, cane and clay instead of stone. Elevated square or circular fireplaces constructed from puddled clay are always present in the centre of the floors. Occasionally elevated rectangular platforms and seats of hard-burned clay have been found. Changes in architectural details of the superimposed structures suggest changes in cultural occupations, which, as will be seen, are supported by analyses of the evidence. Stairways or ramps lead to the summits of the structures.

In some instances, although these structures were intended to be the town's chief ceremonial house, interments of important individuals in pits beneath the floor-levels were made. Nearly always these are lavishly accompanied by mortuary offerings of pearl and shell beads, copper ornaments, engraved shell gorgets, and other implements and utensils of bone, stone, shell and pottery.

The villages were small, and only in rare instances could the number of inhabitants have exceeded 1,500 or 2,000 individuals. The huts were small and rude, and in close proximity one to another; the dead were buried either at haphazard throughout the village, as in the Chickamauga Dam Basin, near Chatanooga, or in cemeteries, as in central and western Tennessee.

A detailed report on key positions in the Wheeler Basin of northern Alabama which had been excavated under his direction has been made by William S. Webb, with supplements on the geology and topographic features of the region and their effect on aboriginal occupation, by Walter B. Jones, State geologist of Alabama, a study of the physical anthropology and pathology of the skeletal material by Prof. W. D. Funkhouser of the University of Kentucky, and an analysis of the ceramic material by Dr. James B. Griffin, of the University of Michigan[2].

On the general character of the relation of aboriginal occupation and geological and topographical conditions, it may be said that as a rule the principal villages or settlements with or without mounds were on level ground adjacent to rivers or lakes. Often there is an amazing amount of kitchen midden material in one or more portions of each settlement. In Tick Island, for example, refuse reaches a depth of 8 ft. for an area of nearly two acres. Other examples are the shell mounds, composed of shells, animal bones, stones, pebbles, flint chips, fashioned and broken objects, potsherds, fish remains, charcoal and occasional human burials. Mounds of this type are often so much as 200 ft. wide, 600 ft. long and 15–20 ft. high, with 60,000–100,000 cubic yards content, all left over from primitive kitchens. An archæological map prepared on the basis of material collected in a preliminary archæological survey in 1932 shows 237 sites distributed over six counties. The key sites selected for investigation numbered nineteen.

In general terms, the culture or cultures of these sites, of which the excavation is described *seriatim* in detail, may be characterized on stratigraphic evidence as a sequence. The earliest form is a pre-pottery culture, in which the bow had not come into use. Its place was filled by the *atlatl* or throwing-stick. Spear points appear in great number, associated with a broad-bladed flint knife. Apparently bodies were buried without the flesh, though the occurrence of numerous burnt bones need not necessarily denote cannibalism. Above this from a level of 6–7 ft. below the surface was evidence of a culture in which all burials were in the flesh, and with them were associated marine shells, pottery vessels, and copper. In certain instances burials were in a shell midden containing much flint and many potsherds. Frequently the head was detached and alone buried. It is by no means certain that all the burials in the mounds are of the culture with which they are found.

A burial mound in Tick Island was quite in contrast with other sites in the vicinity, having a number of distinctive cultural traits, which cannot be connected with any other sites or known racial stock. Nothing but pottery, surprisingly, was used, and in quantity, for burial offerings. Some burials were flexed, some extended, but the most common practice was the burial of the detached head. All mortuary vessels were shell-tempered, while detached sherds were all gravel- or sand-tempered. The significance of this will appear later. A very unusual open bowl with much elevated strap handles and rows of protuberances has also been recorded on a number of sites along the Tennessee in north Alabama.

The association of outstanding stone artefacts with copper artefacts, particularly copper reel-shaped objects, leads to discussion of the distribution of these last. The practice of depositing these copper reel-shaped objects in burial mounds is found to centre in a comparatively small area, embracing the counties of northern Alabama. A comparison of the sites produces a very constant complex of thirty-six cultural traits, to which on account of the consistent association of copper, especially the reel-shaped objects, and galena with burials, the name of the 'copper-galena' complex has been given. The people of this culture obtained and worked native copper, buried galena with their dead, possessed many ocean shells, practised ceremonial destruction of artefacts and produced woven fabrics. They were either well on the way towards developing a specialized sedentary culture, or else they represent the degenerate form of a higher cultural complex.

In either event, although neither history nor tradition presents any suggestions for their connexion with tribes who later inhabited this territory, it is noted that they occupied the territory where de Soto (1540) reported the Yuchi to be living; while an examination of the traits here considered to be fundamental in the copper-galena complex leads to the conclusion that it may be regarded tentatively as a manifestation of the Hopewellian phase—a phase centring in the Hopewell culture of Ohio, which was the result of the high development of an able people, who over a long period of time "drew to themselves the best cultural and material wealth from a large area, and like many a metropolis of modern times, radiated a powerful influence on customs and techniques to all less-favoured areas".

The reference to the temper of the pottery of Tick Island calls for further elucidation. In the report on pottery by Dr. Griffin, it is pointed out that the distinguishing characteristic most easily definable in the analysis of the sherds from six sites submitted to him was the type of temper ; it was of primary importance in recognizing and distinguishing the culturally complete ceramic types. As a rule, Dr. Griffin points out, temper is not a reliable diagnostic trait. Yet there is, for example, no evidence that the makers of the shell-tempered pottery had any cultural contact with the users of sand or fibre for tempering. Although pottery containing limestone has contacts with that containing clay or grit, such evidence is lacking for sand and fibre, although both types of pottery occur on the same site.

INTERGRADING AMONG PLANTS IN RELATION TO THE PROVENANCE OF FOREST TREES

By Dr. R. Melville,
Royal Botanic Gardens, Kew

It has long been known that the geographical source of the seed of forest trees is important if a well-grown and healthy plantation is to be achieved and yield a profitable return. For some years experimental plantations of European Larch have been grown by the Forestry Commission from seed of several Scottish and Continental sources. Attention has been focused to an increasing degree on the question of seed provenance in an effort to obtain varieties capable of giving high yields under a variety of soil conditions in different parts of the country and able to withstand frosts and fungal diseases. With the object of stimulating interest in the question, a discussion on seed provenance and local races of forest trees had been arranged between Sections K (Botany) and K* (Forestry) of the British Association at Dundee, but did not take place before the cancellation of the meeting.

A considerable volume of research on seed provenance in forest trees has been carried out on the Continent, by far the greater part of which has been concerned with conifers, especially Scots Pine, European Larch and Norway Spruce. Much of the work has had a physiological bias. The relationship of seed source to the complex of characters resulting in frost hardiness and the ripening of the shoots has been studied. Rate of growth and growth periodicity are important also and interact on the quality of the resulting timber. Among the morphological characters compared in strains of different origin are the growth habit and the form of the root system, both of which may have a profound influence on the yield under particular conditions, as well as on the form of leaves, buds and cones. It is not possible here to do more than indicate the extent of the wide field already covered by numerous experimenters, but able summaries are given by Langlet[1] and Kalela[2]. The purpose of this article is to point out the relationship between some recent developments in experimental taxonomy and the question of provenance.

The correlations between morphological characteristics of adult trees of different strains and their sylvicultural value so far attempted have been based in the main on the conception of species and varieties as discrete entities, varying but little and more or less easy of recognition. This is a conception related to the classical taxonomy, in which plant forms are often described from one or a few similar individuals. Frequently this is unavoidable, as when the only specimens available have come from a single collecting expedition in isolated or difficult territory. Nevertheless a somewhat static view of the species as an individual results. In settled countries where extensive investigations of the flora have been made, material is available or can easily be obtained for intensive and critical studies of particular species or species groups. Such studies lead to a more dynamic view of a species as a constantly varying population in which the characters of the component individuals intergrade. To enable the foresters to make the most intelligent use of this intergrading, the taxonomist must first produce a classification in which it is embodied. The recent treatment of intergrading is a step in this direction.

Intergrading may occur within a species or between related species capable of interbreeding.

In the case of intra-specific variation, the individuals composing the species can be arranged in an orderly sequence dependent on the gradation of a particular character or group of associated characters. Huxley[3] has proposed the term *cline* for such graded series, with suitable prefixes to denote different types of cline. In connexion with the provenance of forest trees, the kind of cline likely to become of most general interest is that in which the character gradient is related to geographical distribution. For this Huxley proposed the term *geocline*, though *topocline*, as later suggested by Gregor[4], is preferable since 'geocline' suggests a cline dependent on differences of soil. Also, in the future, it may be necessary to use 'geocline' in the latter sense. Huxley quoted as examples of topoclines the intergrading between the wrens of the Shetlands, Fair Isle, the Orkneys and mainland of Britain, with several more among animals, but none in plants. The occurrence of geographical character gradients, however, is probably as common among plants as animals, and little research is necessary to bring them to light. The cedars, for example, form a graded series from west to east beginning with the Atlas Cedar, *Cedrus atlantica*, of the Atlas Mountains, followed by the Cedar of Lebanon, *C. Libani* of the Lebanon Mountains and Cilician Taurus, and ending with the Deodar, *C. Deodara*, of the Western Himalaya. In geographical order the leaves increase in length from west to east, while the number of leaves in each yearly fascicle on the short shoots decreases in the same order (Fig. 1). Hooker, Henry, Dallimore and others considered these forms as varieties of one species, and at the same time retained separate specific names mainly on account of the discontinuous distribution. Continuous variation with geographical gradients probably exists in the European Black Pines, *Pinus nigra* Arnold; the variety in the Pyrenees and Cevennes, var. *cebennensis*, has the longest and most slender needles, the Corsican Pine, var. *calabrica*, has needles of intermediate length and thickness, while the Austrian Pine, var. *austriaca*, has the shortest and stoutest needles of the western European forms. In North America the southern forms of the Shagbark Hickory, *Carya ovata*, have pubescent leaves and branchlets, while forms in the northern United States and Canada are glabrous or nearly so. An examination of the available herbarium material revealed some intermediate forms from the intervening States, and it seems probable that a north to south gradient exists in degree of pubescence in this hickory.

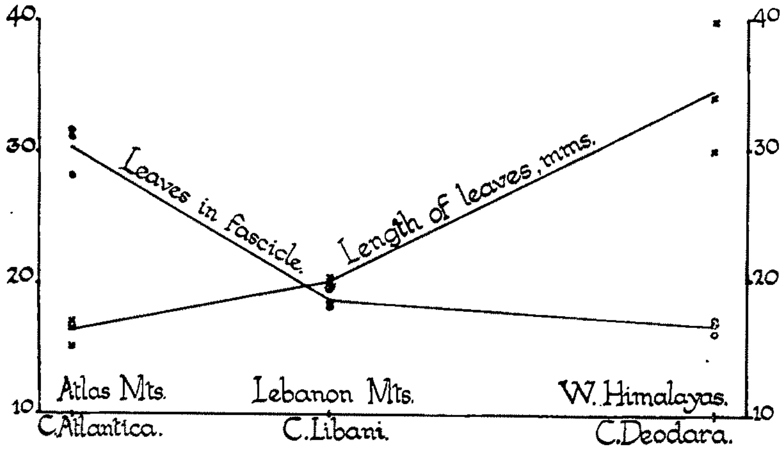

Fig. 1.

TOPOCLINES IN CEDRUS. MEAN CURVES FROM THREE TREES OF EACH FORM, GROWN AT KEW, SHOWING GRADIENTS IN MEAN NUMBER OF LEAVES PER ANNUAL FASCICLE ON SHORT SHOOTS AND MEAN LENGTH OF LEAVES OF SHORT SHOOTS IN MILLIMETRES.

Lindquist[5] mentions a north to south gradient in the leaf shape of the common Wych Elm, *Ulmus glabra* Huds., which in the northern parts of its range in Europe has narrow leaves and in southern parts broad leaves. Field work in Great Britain has confirmed the existence of a north to south topocline in leaf and stem characters in this elm. From Durham northwards spontaneous or subspontaneous individuals bear relatively narrow leaves (ratio of length to breadth 100 : 53–39 or less) and branchlets sparingly pubescent with long internodes. South of the Thames, the common form has relatively broad leaves (ratio of length to breadth 100 : 54–63 or more) and the branchlets are densely pubescent and have shorter internodes. Through the intervening area, forms intermediate in character occur, and there is some intermingling of broad-leaved and narrow-leaved forms as well. Owing to the frequency with which this species is planted, it is not possible to decide whether or no the intermingling of the different forms is a natural phenomenon. Occasional narrow-leaved forms are found in the south and broad-leaved forms in the north, so that it is possible that the proportions of the various forms in the population change in a regular manner from north to south in much the same way as with the bridled and normal forms of the guillemot. There is no doubt, however, of the existence of the gradient in leaf-shape with its associated characters, and a somewhat similar gradient exists in at least one other British species of elm.

Intergrading between species due to hybridization, segregation and backcrossing is well known among plants and gives rise to difficulties for the taxonomist in such genera as Ulmus, Salix and Nothofagus. The intermediate forms normally have a random distribution in the area common to both parents, but they can be arranged in graded sequences analogous to naturally occurring clines by taking advantage of a suitable character, for example, leaf shape in Ulmus. For such an arrangement of hybrid forms, Melville[6] proposed the term *nothocline* and described a nothocline based on the variation of leaf shape in the numerous forms of the hybrid *U. glabra* Huds. × *U. Plotii* Druce. The primary need for a method of classifying hybrid swarms can thus be satisfied. The road is opened for attempts to correlate other characters, such as properties of the timber or resistance to disease, with the variable character on which the nothocline is based.

The arrangement of the individuals composing a species into clines enables the taxonomist to present the data of variation in a form in which it can readily be grasped. The sylviculturist may be able to draw useful conclusions from such data. Thus it is probable that glabrous forms of the Shagbark Hickory are more hardy than pubescent forms, while some at least of the intermediate-leaved forms of the Black Pine are the most desirable sylviculturally. If it proves feasible for the taxonomist to define ecoclines—a gradient related to conditions of the habitat—in woody species, some help may be afforded in the choice of the most suitable form for a particular site. A study of the European Larch on these lines would be useful. Until further work has been done on hybrids, the value of the nothocline remains problematical, though it seems probable that when linkage exists between morphological and sylvicultural characters, it will be revealed by the groupings arrived at in this type of classification. If this proves to be the case, the taxonomist may be able to indicate the best forms for propagation from the numerous wild forms in such hybrid swarms as those connecting the elms, *Ulmus glabra* and *U. Plotii*, and the common pedunculate and sessile oaks, *Quercus Robur* and *Q. petraea*.

OBITUARIES

Prof. C. Białobrzeski

PROF. CZESŁAW BIAŁOBRZESKI, who was recently executed by the German authorities in Poland, came from a family of Polish country squires, settled in the Ukraine. He was born in 1879, when the Ukraine was a province of the Russian Empire. His earlier scientific and academic career was spent in the University of Kiev. Like other selected candidates for professorships he was sent abroad to continue his training. Langevin was the man to whom he chose to be attached. To Białobrzeski, he was the embodiment of the ideal physicist, the man uniting philosophical clarity and vigorous theoretical penetration with fine understanding of experimental work. Białobrzeski was all his life a faithful admirer of Langevin, in spite of a fundamental difference of views in everything but physics.

At Kiev, Białobrzeski held his first two appointments, as *Privat-docent* and assistant professor. After Smoluchowski's premature death, the University of Cracow chose Białobrzeski to be his successor. It was, however, not until a year or two after the end of the Polish-Bolshevik War that many Poles living in Soviet Russia were allowed to leave for Poland. Białobrzeski was among those repatriated. He was appointed professor at the University of Cracow; but a year later he answered the call to the capital. He settled in Warsaw, as professor of theoretical physics in the University, a position which he held until his death.

Theoretical physicist though he was by virtue of his appointment, he could never face being severed from a general physical laboratory. After some struggles, he had a laboratory of his own, well equipped and staffed with talented young people. The work of this laboratory is well known to every specialist in spectrography or dielectrics.

Białobrzeski published few papers. The subjects treated in his papers during his professorship in Warsaw were stellar radiation, absorption and diffusion of light, and dielectrics. His last papers were on cosmic ray bursts and on ionization in liquid dielectrics.

Białobrzeski was a very active member of the International Institute of Intellectual Co-operation, an organ of the League of Nations. Owing to his efforts, and undoubtedly to the keen interest he took in philosophical problems, about thirty leading theoretical physicists from Europe and America were invited to Warsaw by the Institute of Intellectual Co-operation for the purpose of discussing the philosophy of physics. This meeting took place on May 29–June 2, 1938, under the presidency of Prof. Białobrzeski.

He was a member of the Polish Academy of Sciences and several times president of the Polish Physical Society.

M. MATHISSON.

Dr. H. J. Walke

Dr. Harold Walke died in Liverpool on December 21 from the effects of an electrical shock received while working in the Physics Laboratory of the University. He was twenty-eight years of age.

Dr. Walke was educated at the Plymouth Corporation Grammar School and University College, Exeter. He early developed an interest in the growing subject of nuclear physics, and he published in quick succession a number of papers and notes which, while perhaps speculative and uncritical, revealed a fertile mind and a very fresh enthusiasm. In 1935 he was awarded a Commonwealth Fund fellowship and this gave him his first opportunity for experimental work in nuclear physics. He proceeded to the Radiation Laboratory, Berkeley, where he worked for two years under the direction of Prof. E. O. Lawrence. [Dr. Walke appears in the illustration of one of the Berkeley cyclotrons on p. 126 of this issue.] He published a number of excellent papers on artificial radioactivity produced in elements from potassium to vanadium.

Walke returned to Great Britain in 1937 to work in the Physics Laboratory, Liverpool, and in 1938 he was awarded an 1851 Exhibition senior studentship. He helped in the construction and operation of the cyclotron and, in addition, he continued his investigations into the activities induced in scandium, titanium and neighbouring elements, making some interesting discoveries in connexion with nuclear isomers and with the process of electron capture. He spent the summer of 1939 in Berkeley and returned in December with much work in hand and full of plans for the future. He had before him a career rich in promise, and his death at so early an age is a great loss to physics. Friendly and unassuming in manner, yet full of a vigorous and burning enthusiasm for his work, Walke was a delightful colleague. He is mourned by many friends both here and in the United States.

Mr. Douglas H. Baird, C.B.E.

Douglas Heriot Baird, managing director of Messrs. Baird and Tatlock (London), Ltd., died on January 3, at fifty-six years of age. The direction of such a business implies a wide knowledge of laboratory practice and of scientific progress. Mr. Baird was well endowed in these respects by virtue of education at Charterhouse, University of London and Karlsruhe (under Engler), and also by twenty-seven years' experience in the business, nineteen in succession to his father, the late Mr. Hugh Harper Baird, who founded it in 1879.

The business being world-wide, Mr. Baird travelled extensively—Canada, the United States, India, Ceylon, Burma, etc.—believing that requirements peculiar to overseas trade can only be properly satisfied by an intimate acquaintance with the local conditions. In these countries, and in those of Europe, Mr. Baird had many friends, and it is safe to say that he met at one time or the other almost every well-known director of a laboratory. During the War of 1914–18, Mr. Baird, besides running a poison gas filling factory, did important work in connexion with field laboratories. He designed the first mobile bacteriological laboratory sent out to France, and was responsible for the improvements in this, and the planning of other special laboratories for the use of the Army Medical Service of the Allies. He was created a Commander of the Order of the British Empire for his services.

After the War, Messrs. Baird and Tatlock became associated with Messrs. Hopkin and Williams, Ltd. A complete new series of the well-known catalogues were issued and the works at Walthamstow were rebuilt. During the past year a six-story annex to their warehouses in Cross Street, Hatton Garden, E.C. has been erected. One floor of the new building is occupied by laboratories of the company's own design and construction.

The work carried out in these laboratories comprises the testing of apparatus, chemicals and materials for laboratory construction; preparation of standard solutions, microscopic stains, indicators, and special reagents; research in chemical manufacturing methods; and the preparation of some of the rarer chemicals (chiefly organic). Special attention is being devoted to the last-named section, which has already turned out a large number of new products, some of which have not previously been obtainable in Great Britain.

Last year a new branch of the firm was opened in Calcutta to deal with increasing trade in the East, and in England the Hopkin and Williams' chemical side has been developed by building two research laboratories in Cross Street, and one semi-industrial research laboratory which is a liaison between the investigating laboratory and the work for elaboration of new processes.

Mr. Baird was chairman of the British Chemical Ware Manufacturers' Association, this year being his twelfth in office, and a member of the Standards Committee of the Institute of Chemistry, and of a number of other bodies associated with scientific affairs and apparatus.

We regret to announce the following deaths:

Mr. J. E. Dowson, known for his work in connexion with producer gas, on January 3, aged ninety-five years.

Prof. L. Hopf, professor of applied mathematics in the University of Aachen until 1933, on December 21.

M. Max Laubeuf, member of the Section of the Applications of Science to Industry of the Paris Academy of Sciences, a pioneer in the development of the modern submarine, aged seventy-five years.

Mr. Reginald A. Smith, keeper of the Department of British and Medieval Antiquities in the British Museum during 1927–38 and director of the Society of Antiquaries, on January 18, aged sixty-six years.

NEWS AND VIEWS

Dr. C. H. Desch, F.R.S.

PERHAPS the outstanding characteristic of Dr. C. H. Desch, who retired from the post of superintendent of the Metallurgical Department of the National Physical Laboratory at the end of last year, was the astonishing—possibly unique—breadth and depth of his scientific knowledge and interests. Educated at the Finsbury Technical College, the University of Würzburg and University College, London, as a chemist, he entered the Metallurgical Department of the last institution in 1902. From 1909 until 1920 he was at the University and Royal Technical College, Glasgow. In 1920 he was elected to the chair of metallurgy in the University of Sheffield, a post which he held until 1931. Thus from 1902 until 1931 he was almost continuously engaged in metallurgical teaching and research.

Although primarily a metallographer, Dr. Desch's knowledge of the more practical aspects of metallurgy is wide, and his contributions to discussions are invariably welcomed by those engaged in industry. Alongside his metallurgical work, however, Dr. Desch has retained his interests in every branch of chemical advance; but the chemistry of cements and concrete, the intermetallic compounds, and the crystalline state in general have claimed his chief attention. The respect in which his scientific abilities have been held may be gauged by the variety of offices which he has filled. From 1926 until 1928 he was president of the Faraday Society; during the winter of 1931–32 George Fisher Baker lecturer in the University of Cornell, while at present he is president of the Institute of Metals and vice-president of the Iron and Steel Institute. Dr. Desch is now scientific adviser to the Iron and Steel Research Council.

Dr. C. Sykes

As chemistry was the avenue which led Dr. Desch into the field of metallurgy, so, in the case of Dr. C. Sykes, his successor as superintendent of the Metallurgical Department of the National Physical Laboratory, has physics functioned. After graduating in science in the University of Sheffield in 1925, Dr. Sykes spent one year carrying out research in physics under Prof. R. S. Milner. After obtaining the degree of M.Sc. in 1926, he entered the Metallurgical Department under Prof. Desch as a Metropolitan-Vickers research scholar. Two papers on the alloys of zirconium published in the *Journal of the Institute of Metals* in 1928 and 1929 appear to represent the first fruits of his work as a metallographer.

Since 1928, Dr. Sykes has been connected with the research organization of Messrs. Metropolitan-Vickers Electrical Co., Ltd., being engaged at first on work on high vacua, thermionic valves and X-ray tubes. About 1934, under the influence of Prof. W. L. Bragg, he began to publish in the *Proceedings of the Royal Society* and the *Journal of the Iron and Steel Institute*, and later in the *Proceedings of the Physical Society* and the *Journal of the Institute of Metals*, a remarkable series of papers on the super-lattice, the order-disorder change in β-brass and other alloys, on the supposed low-temperature critical points in iron and steel and on age-hardening. Some sixteen papers, all of real importance, represent the contribution which Dr. Sykes has made in little more than five years to that field of knowledge which is concerned with the physics of the metallic state.

Baron Richerand (1779–1840)

BARON BALTHASAR ANTHELME RICHERAND, a famous French surgeon, was born at Belley in the Ain Departement on February 4, 1779. He studied medicine in Paris, where he qualified in 1799 with a thesis on fractures of the neck of the femur, and two years later published his "Nouveaux Élémens de Physiologie", which met with a remarkable success and went through thirteen editions and was translated into seventeen foreign languages. In 1802 he was appointed assistant surgeon to the Hôpital Saint-Louis, where he later became surgeon-in-chief. In 1805 appeared his "Nosographie et Thérapeutique chirurgicales" in three volumes, of which the sixth edition was published in 1821. In 1807 he was made professor of surgical pathology in the Paris medical faculty, where he continued to lecture for more than thirty years.

In acknowledgment of the care which he had bestowed on the Russian and German wounded in 1814 in the Hôpital Saint-Louis, which had become converted into a huge ambulance, Richerand was made Commander of St. Anne and Knight of St. Wladimir by the Emperor of Russia and received the Military Order of Frederick from the Grand Duke of Baden and a gold medal from the King of Prussia. In 1824 he was appointed surgeon to Louis XVIII and in 1829 hereditary baron for his services to science and humanity. His minor works included "Des erreurs populaires relatives à la médecine" (1810) and "Histoire des progrès récents de la chirurgie" (1825). He also wrote notices of Bordeu, Cabanis, Brillat-Savarin, Ambroise Paré, etc., and a large number of articles in the "Dictionnaire des sciences médicales", *Mémoires de la société d'émulation*, *Bulletin de la Société philomathique, etc.* He died on January 23, 1840. A posthumous honour was paid to him in 1851 when the Avenue Saint-Louis was renamed after him.

Utilization of Scientific Research during War

IN the House of Lords on January 18, Lord Strabolgi asked the Government questions on the methods being adopted to examine 'war inventions',

Vol. 145 SATURDAY, JANUARY 27, 1940 No. 3665

SHORT REVIEWS

BIOLOGY

The General Aspects of the Vegetation of Europe

By Marietta Pallis. Pp. iv + 66. (London: Taylor and Francis, Ltd., 1939.) 3*s.* 6*d.* net.

IN this essay, Miss Pallis endeavours to assess the various factors which have determined the character of the existing vegetation of Europe. She naturally places in the foreground the climatic factors, particularly the rainfall, which according to Schimper governs the development of woodland and grassland respectively. For Europe, with its comparatively abundant rainfall, woodland should be dominant. But this dominant vegetation which Miss Pallis calls primitive has been considerably modified by the action of animals and man, both in historic and in prehistoric times. Miss Pallis thinks that Schimper did not appreciate sufficiently the enormous effect of such action, to which he only refers incidentally. The fact that much of the present vegetation of Europe is of a secondary or degenerate type caused by animal and human interference seems to the author to be of far-reaching importance.

Farrow's experiments on the vegetation of the Breckland have demonstrated the modifying effect of rabbits, and Miss Pallis in her essay directs attention to many other instances of the change in vegetation produced by man and domestic animals, particularly goats, in other parts of Europe—Thessaly and Greece being especially chosen as examples.

But apart from what is going on at present, Miss Pallis indicates that such changes may have been occurring for an indefinite length of time, long before human interference occurred. The disappearance of the forest covering the greater part of Europe began gradually, she believes, with the appearance of herbivorous animals and gained in speed towards the end of the Tertiary period, when the grazing horse took the place of the browsing horse. The appearance of these horses coincides with the progressively falling percentages given by Mrs. Reid and Miss Chandler for the woody plants of the Tertiary.

In a table at the end of the publication, Miss Pallis sets out clearly some of the facts on which she bases her conclusions. Her essay, in which a great many facts have been gathered together, both from her own observations and from those of others, gives much food for reflection, and should be carefully studied by all ecologists and plant geographers.

Wild Chorus

Written and illustrated by Peter Scott. Pp. x + 120 + 68 plates. (London: *Country Life*, Ltd., 1939.) 21*s.* net.

THE pictures take the stage in this attractive book, and the text makes an appropriate background. The writing is simple and direct, and whether the author takes us after geese in the mud-flats of the East Anglian coast, on the plains of Hortobagy, on the Black Sea or in Persia, or merely describes the return of Annabel or Barnacle Bill, or the punting risks encountered at the railway bridge, he manages always to convey a sense of adventure and a feeling of enthusiasm in his exploits.

Few artists have been able to catch the attitudes and colour patterns of birds without losing spontaneity by paying too great attention to feathers; but Peter Scott has this gift. He is too familiar with his ducks and geese to miss their particularities, and his fine appreciation of design and of the effect of masses of light and shade are strikingly shown in such pictures as "Pink feet paired", "Blue Sky and Snow Geese", and "Four Teal". The colouring varies considerably in quality: among the most successful are "La Toilette", a picture of two pink-footed geese upon wet sand, "Garganeys in Spring", and the subdued yellows and greys of "Geese moving from Stubble to Potatoes". But in some, while the action and grouping of the birds themselves are beyond criticism, the treatment of clouds and water is harsh and the colours strong even to hardness. There are two fine sepia reproductions of water-colour drawings, flamingoes and Caspian pelicans, and the quality is so delicate that one could have wished that a coloured plate had been spared for a water-colour.

An odd mis-spacing occurs in the legend of the plate facing p. 10, "BRENT GEESE COMING OFF THE ZO STERA", which suggests an exotic lake rather than a common water-weed.

To anyone who delights in lively narrative and in the colouring, action and groupings of geese and ducks in the air or on water or land, this work will afford great pleasure. JAMES RITCHIE.

A Book of Roses

By J. Ramsbottom. (The King Penguin Books.) Pp. 30+16 plates. (Harmondsworth: Penguin Books, Ltd., 1939.) 1*s.* net.

THIS charming little book reproduces most excellently in octavo size sixteen coloured plates by that master of botanical portraiture Pierre Joseph Redouté, whose magnificent three-volume work "Les Roses" was published in thirty parts between 1817 and 1824. In addition to the exquisite reproductions, there is for each of the roses figured a short account giving botanical and horticultural information.

Of Redouté himself there is a good account. His career is full of interest. Shortly before the French revolution he came over to England to learn the English methods of stipple engraving not then used in France.

The major part of the text of the "Book of Roses" is devoted to the history of this queen of flowers. The earliest known European representation of the rose is found in the House of Frescoes at Knossos, dating from the middle of the sixteenth century B.C. The ancient coins of Rhodes had figures of roses, which flower gave the name to the island. Herodotus and Theophrastus, the father of botany, both give accounts of the rose. From these early representations and descriptions of the rose through Roman and medieval times to the present day, Dr. Ramsbottom follows up carefully and delightfully the history of the rose. His very readable and informing text seems to refute a passage of Walter de la Mare:

> . . . . . . "No man knows
> Through what wild centuries
> Roves back the rose".

The "Book of Roses" is sure of a warm welcome, and the publishers are to be congratulated on their production of this most charming little book.

The World of Plant Life

By Prof. Clarence J. Hylander. Pp. xxii+722. (New York: The Macmillan Company, 1939.) 32*s.* 6*d.* net.

PROF. HYLANDER, in his preface to this volume, says that it was "planned and written with the specific purpose of making the layman familiar with a few of the interesting plants, both native and introduced, which are found in the United States". He has purposely avoided using unnecessary technical terms, and has written throughout in a style that will appeal to the non-scientific reader. Indeed, in some instances he is perhaps too lax in his statements, as when he says in his preface that "Gardening is a fundamental instinct", a view that few psychologists would support!

After an introductory section on the whole plant kingdom, Prof. Hylander works step by step through the various groups, commencing with bacteria, and following more or less the system of Engler. As end-papers there are phylogenetic 'trees' showing the supposed lines of plant descent from fission plants to palms and pinks. It is perhaps a pity to include these in a popular work, as many readers will assume that such trees rest on a firmer foundation than is actually the case. This is especially so if Engler's system is used, as Engler himself was definitely sceptical regarding its phylogenetic basis.

Under each family Prof. Hylander mentions a number of genera and species of special interest to American readers, and the information he gives will undoubtedly provide a useful scientific background for the study of American vegetation, both native and introduced.

The illustrations are excellent, and special mention should be made of the attractive silhouettes at the head of each part.

Looking at Life

An Introduction to Biology. By A. M. S. Clark and G. Buckland Smith. Pp. xvi+224. (London: J. M. Dent and Sons, Ltd., 1939.) 2*s.* 6*d.*

THE cinema has now come to be regarded as a valuable tool in the construction of a biological education. The visual images that the viewer carries away with him are necessarily more stimulating and dynamic than the static photographs of text-books. But the transitory character of a film-showing has a disadvantage in that if a mistake in visual memory is made by a pupil it may well persist, so that the aim of the authors of "Looking at Life" in supplying an elementary book which could be used as a complement to the already available biological films is admirable.

Unfortunately, the text of the book contains little more than a potted version of the more rigid university botany and zoology courses and is scarcely suitable to serve as a first course in biology. Animal and plant types are described in a manner completely unrelated to any local environmental conditions, so that a syllabus based on this book would be, at least with regard to the animals, almost entirely theoretical, or would have to rely largely upon museum specimens. Better use of already existing films would have been made if the framework had been constructed around representative types of freshwater and terrestrial forms which are likely to be available. The text itself is a strange mixture of clarity and obscurantism, while the complete omission of gymnosperms is peculiar in a book where all the other main plant phyla are described.

CHEMISTRY

Electrochemistry and Electrochemical Analysis

A Theoretical and Practical Treatise for Students and Analysts. By Dr. Henry J. S. Sand. Vol. 1: Electrochemical Theory. Pp. viii + 134. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1939.) 4*s*. 6*d*. net.

THE preface states that this, the first of two volumes, deals with general principles, the second volume being planned to be a guide to modern methods of gravimetric electroanalysis. The present volume provides a clear and sound introduction to electrochemistry and covers all the theoretical matters which will arise in the practical part, some of which are not very well explained in other books. The section on transport numbers is good and the concentration changes at electrodes dealt with in Chapter vii are clearly explained. The modern theory of electrolytes is briefly yet adequately dealt with, but it is unfortunate that both the equations given on p. 64 are incorrectly printed. Some expressions are peculiar; for example, on p. 57 the 'valency of a reaction' is mentioned, and the system of numbering of the equations is sometimes rather puzzling. The book will be particularly useful to analysts who have to use the electroanalytical methods and have not kept up to date in electrochemical theory, whilst all students will welcome the concise and clear way in which the principles of the subject are discussed.

Aids to Organic Chemistry

By Stanley F. Smith. (Students' Aids Series.) Second edition. Pp. viii + 120. (London: Baillière, Tindall and Cox, 1939.) 3*s*. 6*d*.

THE second edition of this useful little work has been revised, the sections on sugars and complex aromatic compounds have been re-written to bring them up to date and give the modern ideas on their structural formulæ, and the index has been enlarged. The author, however, has been careful not to expand the text so as to change the character of the book. The volume provides a concise summary of organic chemistry which will be very useful to medical students in the preparation and revision of the subject, and it is a useful supplement to text-books which deal with the topics in more detail.

The Economics of Chemical Industries

By Dr. Edward H. Hempel. Pp. ix + 259. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 15*s*. net.

IT is regarded at least as important to be able to sell an article as to make it: indeed the salesmen are more highly remunerated than the technical workers. Whilst personality is the greatest asset for a salesman, there is growing up a science of salesmanship and management which is evidenced by the increasing number of books dealing with various aspects of the subject.

This particular one seeks to portray the characteristic background and the economics common to the American chemical industries. It is very informative and will be of great value in its country of origin and of interest elsewhere to firms which have business connexions with the American chemical industry. It deals largely with legislation, foreign chemical trade, and financial policies, and contains a considerable amount of statistical matter. A similar volume based on British customs would have wide appeal.

ENGINEERING

(1) Lehrbuch der Hochfrequenztechnik

Von Dr. Fritz Vilbig. Zweite verbesserte und erweiterte Auflage. Pp. xxviii + 1019. 35.80 gold marks.

(2) Schrifttumsverzeichnis zum Lehrbuch der Hochfrequenztechnik

Von Dr. Fritz Vilbig. Zweite verbesserte und erweiterte Auflage. Pp. iv + 172. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1939.) 8 gold marks.

THE publication of Dr. F. Vilbig's monumental text-book on high-frequency phenomena two years ago provoked expressions of general and well-merited approval, for it was clear that its author had successfully attempted the difficult task of surveying, in up-to-date fashion, a field already extensive and yet expanding. In particular was his effort commended for the judicious balance of his selection of material, old and new. Two years is a long time in wireless history, so that it is not at all surprising that Dr. Vilbig has already been obliged to undertake the preparation of a second edition (1) of his book. The changes made are naturally mainly by way of additions, the chapters being expanded on the average by a fifty per cent increase of text, though naturally the expansion is relatively greater in the case of such swiftly developing subjects as the study of wave propagation and television. An entirely new chapter on modern acoustics has, however, been added at the end of the book.

In Dr. Vilbig's first edition a most comprehensive and up-to-date bibliography of books and original papers occupied no less than a hundred pages. In view of the expansion of the main text in the second edition, it has become necessary to publish this bibliography as a separate volume (2), which is, of course, correspondingly enlarged and brought up to date.

Radio Interference Suppression

By G. W. Ingram. Pp. viii + 154. (London: The *Electrical Review*, Ltd., 1939.) 5*s*. net.

IT is not often that one branch of applied science reacts so unfavourably on another branch, and the difficulties which have arisen from the interference from power circuits and apparatus in the prevailing types of radio-receivers were scarcely anticipated. The problem assumed international magnitude, and has only within the last few years been brought down to a qualitative basis. Meanwhile the British Post Office has been investigating and advising on tens of thousands of cases per annum, and it is to them that we owe the idea that the interfering radio currents travel along power and other mains longitudinally, that is, along the wires in parallel; indeed, the impedance to earth of such mains may be megohms, thus conserving the disturbing energy. The variegated field has now been sorted, and a very complete guide offered by the present author, whose firm has been in the forefront, both in theory and practice, of interference suppression. In principle the methods are simple, the application of condensers to earth, with or without appropriate chokes, being most general; the economic design of units and their proper location, however, requires systematic thought. Much of the author's information is usefully tabulated. L. E. C. H.

Applied Acoustics

By Dr. Harry F. Olson and Frank Massa. Second edition. Pp. xviii + 494. (London: Constable and Co., Ltd., 1939.) 25*s*. net.

AMONG the most important applications of science in commercial engineering is sound-films, and the Radio Corporation of America, which has the services of the authors in high executive capacity, has always shown initiative and independence of the Western Electric, its major competitor, in improving sound recording and reproduction both as a whole and on the scale demanded by cinema-goers. The new edition is a somewhat expanded version of the first edition, with the necessary sections brought up to date. The text is most readable and remains the best summary of technical applications of what was long considered to be an academic scientific subject. The side-issues are many, including the measurement of noise, the control of transmission of sound vibrations through building structure, much physiological acoustics, and sound-signalling. The print and diagrams are both excellent. L. E. C. H.

GEOLOGY

Outlines of Historical Geology

By Prof. Charles Schuchert and Prof. Carl O. Dunbar. Third edition, entirely rewritten. Pp. v + 241. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1937.) 12*s*. 6*d*. net.

THIS book provides a summary of geological history; but it must be stated at once that this history has special reference to North America, since mention—and that brief—is made of only a few non-American topics or examples. It is not intended for the specialist, its aim being to provide a short general survey of earth-history. As the authors say, their intention is to bring into relief the high lights of this history, and this they certainly succeed in doing.

The story is presented in four parts, the first dealing with the nature of the evidence, the second with the physical history and the third with the history of life. The sections concerned with the later episodes of geological history have deliberately been made fuller than usual in a book of this size, this added detail leading up to the fourth part of the book, in which man's geological history is considered The account of the evolution of mammals, includin man, is especially well done. As usual in America text-books, the illustrations are abundant and mostl excellent; a few mistakes have been noted—fo example, there are no Tertiary lavas in the Orkneys

This is an excellent book for a geology studen desiring a summary of North American historica geology, or for the general reader in search of refreshing but authoritative account of the marvellou pageant of life revealed by palæontology.

Geology for Engineers

By Brig.-General R. F. Sorsbie. New edition. Pp xxii + 348. (London: G. Bell and Sons, Ltd., 1938. 12*s*. 6*d*. net.

THE first edition of this book was published in 1911, and while the same general arrangement is retained in the new volume, the former chapters on historical geology have been omitted and the section on applied geology extended, so that it now forms nearly two-thirds of the book. No new illustrations are used, all the diagrams being taken from the old edition. Much material is quoted direct from other authors, and modern treatment of subjects such as clays and soils is lacking. The bibliographies which are given with various chapters would be improved by the inclusion of fuller details and dates; the titles of works published more than sixty years ago could well be replaced by those of more recent text-books.

MATHEMATICS

Elliptic and Hyper-elliptic Integrals and Allied Theory

By the late W. R. Westropp Roberts. Pp. viii + 311. (Cambridge: At the University Press, 1938.) 12*s*. 6*d*. net.

WILLIAM RALPH WESTROPP ROBERTS was the eldest son of the senior fellow of Trinity College, Dublin, and after a brilliant career as a student in which he gained most of the important prizes in the Mathematical School, he was elected to a fellowship at his father's college in 1882. During the remainder of his life he made many noteworthy contributions to mathematics and in later years planned to publish a work embodying his researches. The present volume is the outcome of that aim, but unfortunately, the author did not live to complete his work.

The text is divided into six chapters, the first of which is devoted to some necessary theorems in algebra. Then follows a lucid discussion of some elementary integrals upon which the more general integral is shown to depend. In this chapter, a very interesting and valuable analysis is given of the function $R(z, n) \equiv d\chi/dz - d\chi/dn$, where χ denotes $A_0\{f(z) - f(n)\}/(z - n)$, which is essential to the development of the subsequent theory. Chapter iii is devoted to algebraic equivalents and Abelian transcendents. The text then passes to Abelian or hyper-elliptic integrals, in which there is a clear investigation of their periodicity. Finally, Chapters v and vi are concerned with the particular cases in which $m = 2$, giving rise to elliptic integrals and functions, and $m = 3$ of the general polynomial $f(z)$ which occurs under the square root in the denominator of the integrand. Each chapter closes with a set of examples for the student's use, and among these may be found some important theorems.

It is evident that the work is not complete as there are several references to Chapter vii and the figures contained therein, but this chapter was never written nor were the diagrams drawn. In spite of this, however, the book is not only a striking essay in mathematical analysis, but is also a notable contribution to the subject. F. G. W. B.

Étude critique de la notion de collectif

Par Prof. Jean Ville. (Monographies des probabilités, Fascicule 3.) Pp. iv+144. (Paris: Gauthier-Villars, 1939.) 75 francs.

THERE are many ways, none altogether satisfactory, of defining probability, but roughly speaking, these fall in two groups, namely, those based upon the 'equally-likely' concept of Laplace, and those based on the concept of frequency. In recent years the frequency method has been greatly developed by von Mises, who introduced the notion of a *collective*. This is defined as a mass phenomenon or an unlimited sequence of observations such that the relative frequency of a particular attribute tends to a fixed limit unaffected by any place selection or gambling system. The probability of the attribute in the given collective is then defined as this limit. It is claimed that this treatment avoids the logical difficulties inherent in Laplace's method.

M. Ville makes a careful analysis of the ideas of von Mises, and also of those of Reichenbach, Popper, Copeland and Wald, who have put forward closely related theories. The conclusion is that the idea of a collective, though roughly what is needed, is too rigid. In particular the use of the word limit, in the strict mathematical sense, either leads to results which are inconsistent with themselves, or at best necessitates a set of artificial restrictions which are really alien to the nature of the problem. A satisfactory definition of probability has not yet been found. H. T. H. P.

Orthogonal Polynomials

By Prof. Gabor Szegö. (American Mathematical Society, Colloquium Publications, Vol. 23.) Pp. ix+401. (New York: American Mathematical Society, 1939.) 6 dollars.

ORTHOGONAL polynomials were first studied in connexion with a certain type of continued fractions, bearing the name of Stieltjes. They are closely related to problems of interpolation and mechanical integration, and recently have come into prominence in connexion with mathematical statistics and quantum mechanics. They are also connected with trigonometric, hypergeometric, Bessel, and elliptic functions, and occasionally occur in the theories of differential and integral equations. The present book is the first in the English language on the subject, and indeed the first extensive treatment of the subject in any language. It deals both with special orthogonal polynomials, such as those of Jacobi, Laguerre, and Hermite, and also with the general theory. In particular, there is an account of recent investigations of the distributions of the zeros, of asymptotic representations, of expansion problems, and of certain questions of interpolation and mechanical integration. Some of the results not previously published are due to the author himself. The book concludes with a set of sixty problems, a bibliography, and an index. H. T. H. P.

Mathematical Tables

Vol. 7: The Probability Integral. By W. F. Sheppard. Completed and edited by the Committee for the Calculation of Mathematical Tables. (Published for the British Association for the Advancement of Science.) Pp. xi+34. (London: Cambridge University Press, 1939.) 8*s*. 6*d*. net.

THESE tables are concerned with the values, from $x = 0$ to $x = 10$, of the functions

$$F(x) = \frac{1}{\sqrt{(2\pi)}}\int_x^\infty \exp(-\tfrac{1}{2}t^2)dt,\ z_x = \frac{1}{\sqrt{(2\pi)}}\exp(-\tfrac{1}{2}x^2).$$

Tables I and II give the ratio $F(x) : z_x$ at intervals 0·01 and 0·1 for x and to 12 and 24 decimal places respectively.

The remaining four tables give natural and common logarithms of $F(x)$. Interpolation is facilitated by the tabulation of derivatives or differences.

The Committee's amplification of Sheppard's work consisted in the completion of Table I and the computation of Table VI.

"The Committee believe that the completion and publication of his tables of the probability integral constitute just that memorial to Sheppard's unsurpassed labours in the field of Mathematical Statistics, which he would himself most greatly have appreciated."

METEOROLOGY

The Drama of Weather

By Sir Napier Shaw. Second edition. Pp. xiv+307. (Cambridge: At the University Press, 1939.) 10*s*. 6*d*. net.

IT is evidence of the growing interest in meteorology that this book should within five years have been reprinted and have now reached a second edition, enlarged by the addition of two chapters with the titles "Where our Rain Comes From" and "Chapter and Verse for Weather in Relation to Agriculture".

The added chapters carry on the happy traditions of the previous portion, the fresh and picturesque language, the concrete as opposed to the abstract statement, and the use of ingenious diagrams containing data that other writers have not attempted to embody. Such diagrams bring into prominence facts which might remain unnoticed if their discovery depended on a severe study of columns of figures; for example, Fig. 93 (p. 258) reveals at once that in the British Isles places fully exposed to the west winds have much heavier rain in winter than in summer, while on the east coast rainfall is more evenly distributed through the year. The author loves a paradox and a note of interrogation regarding widely prevalent ideas. In the first of the new chapters he is certainly successful in stimulating thought when he defends the idea that the pressure distribution is produced by the winds, not vice versa.

The chapter on agriculture contains a number of interesting diagrams. It includes a discussion of the calendar, though it makes no mention of the widely supported World Calendar in which the year consists of four quarters each of three months or 91 days, beginning on a Sunday; in it the 365th day is inserted between December and January.

The book is strongly recommended, to meteorological specialists and laymen alike, for its wide range of appeal, historical and artistic as well as scientific. G. T. W.

Meteorology for Aviators

By Dr. R. C. Sutcliffe. (Air Ministry: Meteorological Office.) (M.O. 432: A.P. 1699.) Pp. xiv+278+27 plates. (London: H.M. Stationery Office, 1939.) 7*s*. 6*d*. net.

THIS publication deals with those aspects of meteorology which are of importance in aviation; but as most of the subject-matter is the common ground of meteorology, the book will appeal to many who are not directly concerned with aviation. It is intended primarily to cover the meteorological syllabuses laid down for the various air navigators' and pilots' licences, and so supplies a long-felt want.

To some extent the information is presented in an encyclopædic, albeit very readable, form, and in this respect the volume recalls the very serviceable Admiralty Weather Manual. The statements that severe hail is "very rare" in the British Isles and that "for really spectacular hailstorms it is necessary to go to tropical and sub-tropical regions" perhaps call for some revision. Hail is a veritable scourge in many parts of central and southern Europe, and in France an elaborate organization for the defence of the vineyards has been in existence for several years (see *Geog. J.*, December 1939, p. 509). L. C. W. B.

PSYCHOLOGY

Psychological Foundations of Personality

A Guide for Students and Teachers. By Prof. Louis P. Thorpe. (McGraw-Hill Series in Education.) Pp. xvi+602. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 21*s*.

THE author is assistant professor of education in the University of Southern California. His book is one of many on personality and compares very favourably with most.

Prof. Thorpe has wisely left out the usual string of illustrative cases which contrive to spoil most books on the subject and are usually a complete waste of time to read. Most readers have ample clinical material of their own; to those who have not, cases usually add confusion and a certain superficiality.

After reading books on personality, the present reviewer always wonders, Is the world any better for all this? Time alone will show.

The Family meets the Depression

A Study of a Group of Highly Selected Families. By Prof. Winona L. Morgan. (Institute of Child Welfare, Monograph No. 19.). Pp. x+126. (Minneapolis: University of Minnesota Press; London: Oxford University Press, 1939.) 9*s*. net.

THIS is a study of the economic stability and psychological adjustments of several hundred families drawn from different parts of the United States. A prior study of the same families was carried out in 1927 and the present investigation was planned with the purpose of discovering any effects due to the intervening five-year period of economic depression (1927–1932). A comparison is made between the earlier and later results. The sample of families was relatively homogeneous as regards socio-economic status. The general outcome, according to the author, seems to favour the family as a social institution.

Biographies of Child Development

The Mental Growth Careers of Eighty-four Infants and Children; a Ten-Year Study from the Clinic of Child Development at Yale University. Part 1, by Dr. Arnold Gesell; Part 2, by Dr. Catherine S. Amatruda, Dr. Burton M. Castner, Dr. Helen Thompson. Pp. xvii+328. (London: Hamish Hamilton, Ltd., 1939.) 15*s*.

GESELL'S valuable contributions to the field of mental growth and developmental norms in infancy need no introduction. The present work by Gesell and three associates is the result of cumulative observations carried out over a period of ten years, on eighty-four infants and children. A wide diversity of cases, mostly typical and touching many aspects of child psychology, is to be found in this study. The primary aim of the authors is to assess the prognostic value of the normative criteria used at the Yale Clinic of Child Development. The book is carefully written and may be recommended to psychologists in Great Britain.

Psychopathic States

By Prof. D. K. Henderson. (Thomas W. Salmon Memorial Lectures.) Pp. 178. (London: Chapman and Hall, Ltd., 1939.) 8*s*. 6*d*. net.

THE Salmon Memorial Lectures for 1938 were delivered by Prof. D. K. Henderson of Edinburgh. They deal in a very fascinating manner with the problem presented by the psychopath and his many bizarre disorders of conduct.

It is difficult to make the lay mind understand that these mental disorders can occur and usually do occur in individuals who are of normal intelligence. They are disorders of conduct and as such are very difficult to deal with; further the law is frequently no help and the individual too cunning to help society, often his greatest enemy.

PHYSICS

Cosmic Rays and Mesotrons

By Dr. H. J. J. Braddick. (Cambridge Physical Tracts.) Pp. x+68. (Cambridge: At the University Press, 1939.) 5*s*. net.

In a subject that has been developing as rapidly as that of cosmic rays, the writing of books is a difficult and often not very fruitful task. Anything in the nature of a treatise is as yet impossible, and treatment of special branches may be out of date by the time a book can be prepared and published. But special circumstances have enabled the author of this work to avoid this pitfall. The small size of the Cambridge Physical Tracts, in this case only 65 pages, calls for extreme condensation, but makes possible rapid publication. Revision has been made to June 1939, so the book may be considered as up to date as is humanly possible. The author does not pretend to cover completely the whole subject. The first part is a useful digest of the more significant experimental results, while the second is a review, from the theoretical side, of the passage of cosmic rays through matter, and in particular of the shower phenomenon. One chapter is devoted to the mesotron, and contains the evidence for assuming the existence of a new particle of mass intermediate between the proton and the electron. There is also a short discussion of its theoretical implications.

A selected bibliography will enable the reader to pursue the subject more deeply.

Absolutkolorimetrie

Von Prof. Dr. A. Thiel. (Arbeitsmethoden der modernen Naturwissenschaften.) Pp. xv+215. (Berlin: Walter de Gruyter und Co., 1939.) 10.80 gold marks.

Prof. Thiel is to be congratulated on the clear and comprehensive account which he has given of his work on the application of colorimetry, which has enabled him to elaborate a technique whereby many inorganic and organic substances can be quantitatively determined optically with an accuracy not before achieved by this method of analysis.

The book is divided into two parts, in the first of which is explained the general principles of colorimetry, the technique used and the apparatus employed. The second section gives details of the practical application of Thiel's method of analysis for the quantitative determination of both inorganic substances and of many organic compounds which are of special interest to biologists and medical workers, notably the vitamins and hormones.

The book is a welcome addition to the essential text-books of chemical and biological laboratories.

A Text Book on Light

By Dr. A. W. Barton. Pp. x+426+6 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1939.) 8*s*.

There are several features of interest in this new book on light by the headmaster of King Edward VII School, Sheffield. The method of presentation is historical, but only "in the sense that the discovery of facts and the development of ideas is presented as they occur historically". There is an unusually good account of Newton's experiments and of his deductions from the facts of observation. It is then pointed out how the mass of evidence grows until one theory fails and another has to take its place. The author adopts the convention as to signs which counts distances measured from the pole of a refracting surface in the *same* direction as the initial direction of the light positive, and the diagrams in the book are drawn with the incident light travelling from left to right so as to give agreement with the usual convention of coordinate geometry. Special mention must be made of the beautiful photographs supplied for the plates by Mr. J. W. Cottingham of Barnsley Grammar School and Dr. J. W. Mitchell of Repton School.

A Text Book of Applied Hydraulics

By Prof. Herbert Addison. Second edition, revised and enlarged. Pp. xii+435. (London: Chapman and Hall, Ltd., 1938.) 21*s*. net.

The issue of a second edition of Prof. Addison's manual is evidence that it has served the purpose which he had in view in writing more especially for "those whose work is not directly connected with hydraulics, but who require to be kept in touch with the main outlines of hydraulic practice".

The new edition makes good a deficiency in the earlier issue in that it contains a useful bibliography of the works to which allusion is made in the text, and there is an additional chapter devoted to propeller and screw pumps. A commendable feature is the number of examples with solutions, numbering 125 and occupying 73 pages. These should be helpful to the teacher, as well as to the student reader who may be working without oral help.

The author is careful to point out that hydraulic formulæ, purporting to be based on identical data, can, and often do, yield different results. This warning is particularly necessary in the case of students and young engineers, who are apt to imagine that a formula is an infallible, as well as a labour-saving, device.

Theoretical Mechanics

A Vectorial Treatment. By Prof. Carl Jenness Coe. Pp. xiii+555. (New York: The Macmillan Company, 1938.) 21*s*. net.

In this book on theoretical mechanics, Prof. Coe, of the University of Michigan, has adopted from the outset the methods and notation of vector analysis, which provide a language common to all the branches of mathematical physics. His aim has been to present an introduction to classical mechanics, and through it to mathematical physics, which shall make clear the postulates on which they rest, and at the same time to explain and apply the basic principles of the vector method. He claims that this approach has proved its value in teaching and enables the student to use vector analysis in his later work. The book, which may be confidently recommended, contains sufficient material for an introductory and an advanced course.

TECHNOLOGY

Principles of Mechanism

By F. Dyson. Third edition. Pp. vii + 364. (London: Oxford University Press, 1939.) 12*s*. net.

FIRST published in 1928 and now already appearing in its third edition, this text-book has fully proved its adequacy for the purpose for which it was written. This was to present the fundamental principles which apply to the moving parts of machines in a sufficiently comprehensive manner to satisfy the requirements of those studying for the engineering degree or for the examinations of the engineering institutions. The line taken by the author was to develop the theory of machines in logical sequence from the well-known principles of mechanics, of which a summary was given in the first chapters. That the third edition exhibits no substantial change in the structure of the book, beyond a number of additions made necessary by the increasing scope of the examination syllabuses, is evidence of the sufficiency of this method of presentation.

The additions fall into two classes, the first of which includes a description, explanation and analysis of the pre-selective epicyclic gear-box. Such an example requires very careful treatment, as each operative gear is a combination of simple mechanisms, and here the method of analysis has been set out in full detail, thus giving the student a lead which should enable him to deal successfully with any other complication of epicyclic gears. The second class of additions comprises several of the more difficult examples of the determination of the acceleration of points in mechanisms. There is an acceleration diagram for a quick-return motion fully explained in the appendix, and as this case is more difficult than that of the simple link mechanisms, this constitutes a very welcome piece of extra information for the student. The exact mathematical analysis of the acceleration of a piston and that of a follower in contact with a cam face of straight or circular outline are also new. What the student will greatly value is the clear, direct, and unambiguous style in which the author expresses himself.

Colour Cinematography

By Major Adrian Bernard Klein. Second edition, revised and enlarged. Pp. xxii + 463 + 42 plates. (London: Chapman and Hall, Ltd., 1939.) 30*s*. net.

IN the previous edition Major Klein gave us, in addition to much information and informed criticism on all aspects of motion pictures in colour, first-hand knowledge of the Gasparcolor system. He has since migrated to the Dufay-Chromex concern and now treats us with details of the Dufay system, the commercial difficulties, and the brilliant way in which they have been met. Perhaps we shall not get the full story of the most used colour process until he is acquired by Technicolor. The text remains a most useful historical summary of the subject, a guide to the present application of scientific principles in a difficult branch of commercial engineering, and a severe criticism of usage. Of particular mention are the Dufay printing and mitigation of moiré, the treatment of beam-splitter cameras, the development of suitable light-sources, and the calculation of filter transmissions. We wish other publishers would emulate the gay colours of the binding.

L. E. C. H.

Wissenschaftliche Photographie

Eine Einführung in Theorie und Praxis. Von Prof. Dr. E. v. Angerer. Zweite gänzlich neubearbeitete Auflage. Pp. vii + 211 + 3 plates. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1939.) 13.80 gold marks.

THIS volume is addressed to the scientific worker who uses photography as a tool rather than to the specialist in photographic technique or theory. Thus the book is written in a style easily understood by anyone with a rudimentary knowledge of physics and chemistry. It describes the nature of the photographic emulsion, its sensitometry and treatment after exposure in considerable detail. The production of the positive print, colour photography and the camera itself are only described to an extent sufficient to make the book complete. This is as it should be, for the main concern of such a book is to guide the experimenter to find the best possible conditions for obtaining the most satisfactory negative. It is, however, more than a photographic manual, for it contains much interesting information for the reader with only a casual acquaintance with photographic methods.

H. W. M.

The Art of Soaring Flight

By Wolf Hirth. Translated from the German by Naomi Heron Maxwell. Pp. 214. (London: *Sailplane and Glider*, 1938.) 5*s*.

AN English translation of the work of Wolf Hirth, one of the pioneers of soaring flight, was called for by reason of the rapid strides made in the art during recent years in Great Britain and America.

The translator says: "No student of soaring flight can ever hope to achieve success without an understanding of certain meteorological phenomena which are clearly explained in this book, and I feel that the reader will find every page both stimulating and interesting". There are accounts of storm-flying and interesting information on the obstruction of fronts by mountain ranges and the like. Sailing in the air, to a greater extent even than on water, raises a host of meteorological questions which would otherwise never be thought of.

L. C. W. B.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS.

to secure co-ordination between the scientific departments of the fighting Services and the Ministry of Supply, and the extent of the co-operation between the British and French Governments in these matters. Lord Strabolgi said he did not wish his remarks to be interpreted as hostile to the Government, and he paid tribute to the strength of the recently appointed Advisory Council of Scientific Research and Technical Development. The reply elicited from Lord Chatfield, Minister for the Co-ordination of Defence, was informative and important as indicating the extent to which the knowledge and services of men of science are being utilized.

Lord Chatfield paid a tribute to the value of scientific research to the Services. The existing establishments were in the main created after the War of 1914–18 or during its later years. They now include many of the leading men of science in the country, either in a working or advisory capacity. He referred to eight research laboratories under the Department of Scientific and Industrial Research, and said: "Generally it is perfectly correct to say that the scientific talent of this country is fully mobilized to its fullest advantage and runs into a very large number of scientists, to be numbered rather in thousands than in hundreds." There is no central organization for dealing with inventions, which actually constitute only a small part of the scientific work in progress. Each Service department and the Air Raids Department of the Ministry of Home Security has its own organization for dealing with inventions, and there is constant consultation between these bodies.

Dealing with the exchange of scientific knowledge between the British and French Governments, Lord Chatfield said that co-operation had begun before the outbreak of war, and that there is now "complete exchange of scientific information". Members of the scientific organizations of the two countries are working in each other's establishments. Further efforts are being made, however, to extend the present liaison. Steps are under consideration to safeguard the interest of inventors, and it is likely that machinery similar to that used during the War of 1914–18, namely, a Commission of Awards to Inventors, would be adopted.

Science and War

PROTECTION of civilian population from attack by deadly weapons that science has created is set forth as one of the paramount duties of science in the present emergency, in the annual report by Dr. Vannevar Bush, president of the Carnegie Institution of Washington, recently issued. The same science which saves life and renders it rich and full, also destroys it and renders it horrible. Is it then possible to remain in a detached atmosphere to cultivate the slowly growing body of pure scientific knowledge, and to labour apart from the intense struggle in which the direct application of science now implies so much for good or ill? As science has produced a weapon, so also can it produce in time a defence against it. Science is dedicated to the advance of knowledge for the benefit of man. Here is a sphere where the benefit might perhaps indeed be immediate, real and satisfying. Can a scientific worker, skilled in a field such that his efforts might readily be directed to the attainment of applications which would afford protection to his fellow-men against such an overwhelming peril, now justify expending his effort for any other and more remote cause?

Although immediate participation of the men of science in the safeguarding of civilization is urged by Dr. Bush, he gives the warning that we should not become stampeded. "There is still a duty to keep the torch of pure science lit, and this duty is only the greater under stress. All the long struggle of a harsh evolution, the pitting of species against the environment, has produced a being whose primary distinction is conscious cerebration, and whose crowning attribute is his intellectual curiosity concerning his complex environment and a thirst for knowledge transcending the mere struggle for existence. If there is no abiding value in a Beethoven symphony, or a theory of the cosmos, or the tracing of an ancient culture, then the Carnegie Institution of Washington has scant reason for existence. If it is really good that man should look at the stars and should contemplate his great destiny, then it is imperative that in those regions which enjoy the blessings of peace the search for the eternal verities should continue."

Recent Earthquakes

AFTERSHOCKS of the earthquake of December 26 in Turkey continue to be felt in widely separated areas. The epicentres are by no means confined to the Erzinjan-Erbaa area, thus lending support to the original estimate from Istanbul of a depth of focus of the original earthquake of the order of sixteen miles. On January 17 eight rather violent tremors were felt in the original area and other violent tremors were experienced at Istanbul, Smyrna, Castamouni, and Izmid. A *Times* report states that at the last-named place an entire hill slid downwards, blocking the road to Kandira. No further casualties are reported from these areas. On January 16 an earthquake occurred at the village of Balcikoy near Nigde, causing two hundred houses to collapse, killing five people and injuring sixteen. The death roll was small because a light foreshock preceded the principal shock, causing people to run out of doors. On January 17 at night, two more violent earthquakes were felt at Nigde, which is in southern Anatolia. These caused four hundred houses to collapse, killing fifty people and injuring a hundred and sixty others. A. Hée of the central seismological bureau, now at Clermont-Ferrand (France), has taken the readings of fifteen observatories and determined the epicentre of the original shock to have been near latitude 39·5° N., longitude 38·2° E.; initial time 26d. 23h. 57m. 23s. G.M.T.

An earthquake of intensity VII, and approaching intensity VIII on the modified Mercalli scale of 1931, was felt in Palermo at 2.18 p.m. (local time) on January 15. Much damage is reported to have been caused to the façade of the monumental church of St. Anna, one of the oldest in Sicily; some damage has been done to the Cathedral, and cracks have appeared in many walls of the poorer type of building. Two people have been killed by falling masonry and twenty-five injured. The electricity supply was temporarily out of action. The earthquake was the most severe for many years, and alarm was caused especially amongst children and people in the poorer quarters of the city. According to a *Times* message, the epicentre of the shock is estimated to have been between Palermo and the islands of Ustica and Alicudi to the north-north-west of Palermo, which would be approximately 38·5° N., 13·25° E. This is in a relatively highly active region seismically, and earthquakes occurred near to this epicentre on August 17, 1926 (38·5° N., 15° E.) and August 21, 1930 (39° N., 14·5° E.). The great Messina earthquake of December 28, 1908, which has been described by Davison, affected this area, according to Baratta, though the epicentre was, of course, somewhat to the east of the present one.

From 1.30 a.m. on January 17, and continuing for three hours at intervals, Paris experienced earth tremors so slight that they were not felt by anyone. The tremors were recorded on the seismographs at the Paris Observatory.

Native Races and Tuberculosis

SOME interesting data bearing upon recent theory of the racial incidence of disease are brought together and discussed in relation to tuberculosis in the *Lancet* of January 13. The older view ascribed the apparently selective action of the infection on native races mainly to innate biological differences, but there is now a tendency to emphasize work and living conditions—with the consequent risk of intense exposure and deficient resistance—on one hand, and the factor of bacteriological immunity on the other. Thus a recent view is quoted in which there is represented a balance between heredity and environment. The emphasis now being laid on social factors, it is suggested, opposes the defeatist attitude that native races are just 'different', and indicates lines of action within human control.

In support of this view, attention is directed to the situation at present in India and Africa. On the Rand, although the incidence among natives working in the mines has fallen considerably in recent years, the incidence among natives in the Union has probably fallen little, if at all. All cases discovered in the mines are repatriated at once and the majority are dead in two years. Thus there is a continuous stream of infectious men returning to the territories from which are derived a return stream of new recruits. There are no sanatoria and little provision of public medical service. In India, a similar situation has arisen in the interchange between urban and rural areas which the growth of industrialism and transport facilities has made possible, with the result that Bengal alone is said to have a million cases of tuberculosis and a hundred thousand deaths annually.

Analysis of the data of the incidence of tuberculosis among non-European or primitives would seem to justify the contention that the problem is now most serious where native agricultural populations are becoming industrialized. That the situation is remediable is indicated by the situation under the Russian Soviets, where rapid industrialization has been accompanied by expansion of the tuberculosis services, with the result that there has been a notable decline in tuberculosis mortality. The writer in the *Lancet* concludes with the admonition that it is the white man's responsibility that the situation in the British Empire should be squarely faced.

Mental Disease in Peru

IN a recent paper (*Amer. J. Psychiat.*, **96**, 403; 1939) Dr. Horatio M. Pollock states that the care of the mentally sick in Peru has gone through a series of progressive stages similar to that in the development of psychiatric science in the United States. A long period of neglect was succeeded by one of inadequate care in almshouses or asylums, which in turn was followed by so-called hospital care with some degree of medical attention, and finally scientific treatment in a modern hospital. The first hospital treatment for mental patients in Peru was provided in the seventeenth century in two general hospitals at Lima, one being St. Andrew's Hospital for men and the other the St. Anne's Hospital for women. Towards the middle of the nineteenth century the special section in the St. Andrew's Hospital became an independent unit with a special physician to look after the patients, and in 1859 a new building named "Hospital de la Misericordia" for mental patients was opened in the outskirts of Lima with accommodation for 160 patients. It was divided into four sections, respectively for quiet cases, those periodically disturbed, mental defectives and epileptics, and violent cases.

In 1918 an entirely new hospital for mental patients, which was named after its benefactor Victor Larco Herrera, was opened at Magdalena del Mare about four miles from Lima with accommodation for more than a thousand patients. The treatment in this hospital has been modernized, and at the present time compares favourably, according to Dr. Pollock, with that in many hospitals in the United States. A single hospital, however, is not sufficient for all the persons requiring mental treatment in Peru. At least two more are needed, and funds are not yet available for enlargement of the present building.

Higher Education in Malaya

"HIGHER EDUCATION IN MALAYA" (H.M. Stationery Office, 2*s*. 6*d*.) is a thorough and most valuable survey. It includes the whole background of teaching and adds an able summary of the resources of the country, mainly due to the rubber plant, and the variety of its population, Chinese, Indians and Malays. The last-named have only been under Western civilization for 60–70 years. They do not dwell in towns like the Chinese. Raffles College, opened in 1928, is the main centre of advanced education, and is increasingly appreciated by parents, who recognize the value of its teaching. One of the difficulties is that English is learnt as a foreign language; so that subject can scarcely be taken, as at the University of London, with Middle English and Anglo-Saxon as necessary adjuncts. It would be like studying Latin in early and medieval sources as well as Virgil and Cicero. The Commissioners urge that the standard of the London degree should be attempted and some modification of the English course allowed, tending to special knowledge of English masterpieces.

The present diploma of the College is not recognized outside Malaya, and not much progress can be achieved without some external assistance in the examinations, which could be managed by the use of air-mail. The professors take leave once in three years, which puts rather a heavy burden on their substitutes, but gives them a chance to meet external examiners. The present arrangements for a president are inadequate, and the "high wastage rate" of failures needs to be reduced. Several drastic improvements are suggested. We regret to notice that science teaching in the schools is generally in a very backward state, and biology has been scarcely begun. The King Edward VII College of Medicine at Singapore is well equipped and does good work within its limits; but it needs a larger scope, particularly regarding public health.

International Journal of Agrarian Affairs

THE first International Conference of Agricultural Economists was held ten years ago. As the period elapsing between meetings is now three years, some means of maintaining an interchange of ideas, beyond the issue of the proceedings, seemed desirable. The *International Journal of Agrarian Affairs*, the first number of which has just been published, is a bold attempt to meet this need. Two numbers will be brought out each year, the intention being to develop a series of studies on economic and social problems, one such problem being dealt with at a time. The *Journal* will therefore serve as a complement rather than an addition to the statistical year-books of agricultural information which are already available. The kind of topics which will form the subject-matter are those common to all countries, and the aim will be to emphasize the universal concern with the solution of such problems, and to discuss them from all possible angles.

The first number deals with the problem of surplus agricultural population. Contributions are made from such widely different localities as Harvard University, Edinburgh, Washington, Quebec, Sofia and Riga. The theoretical basis of the problem is first discussed and an account given of the historical influence of landowning. Other writers stress the effect of policies of restriction on trade and on movements of population between countries, and describe the special problems of Bulgaria and Latvia, while as regards remedies the development of subsistence holdings is advocated. Though not actually the official organ of the International Conference of Agricultural Economists, the *Journal* will be issued free to all members. For non-members the price is 3*s.* 6*d.*, or £1 per volume of six numbers (including postage). All subscriptions and communications should be addressed to the Editor, 3 Magpie Lane, Oxford.

Meteorology in Iraq

THE third annual report of the Director of the Meteorological Service of the Government of Iraq, which covers the year ending March 31, 1939, shows that, owing to the difficulty of obtaining the necessary staff, the basic organization of the Service had not been completed by that date. For example, although new offices were available at Nasiriya and Diwaniya, no staff was available to man them. At the headquarters station at Baghdad, continuous records of wind, temperature, humidity and rainfall were maintained and were analysed and published in the Monthly Weather Report. Upper winds were measured three times a day, and the results appeared in the I.C.A.N. summaries published by the Meteorological Office, London, up to December 1938. After that month they were published in Iraq together with similar summaries obtained from stations maintained by the Air Ministry, Meteorological Service, Habbaniya.

Meteorological information continued to be supplied to civil aviation from Baghdad and Basra, the number of messages rising to 1,200 per month during the winter. As the volume of air traffic over Iraq continued to increase, difficulty was experienced in maintaining this part of the service, and the need for an extension of the existing wireless service was felt. As was only to be expected, the report contains little of purely scientific interest. Owing to the fact that air-conditioning engineers were constantly asking for data concerning the dust content of the air, the Director placed an order for an Owens settlement dust counter and for the necessary microscope for measuring the records.

Lantern Slides

THE cost of making lantern slides from illustrations may be materially reduced by using paper negatives, and Mr. G. H. Bell, of the Physiological Institute, Glasgow, gives an account in the December issue of the *Journal of Scientific Instruments* of a method he has found very satisfactory. He uses "Kodaline Paper Slow" exposed for three minutes at *f*/11, the illustration being illuminated by four 100-watt lamps placed just behind the camera lens. He develops with Kodaline developer and gets a pure black and white negative. He prints on gas-light lantern plates using a mask and giving an exposure of 8 seconds for a surface intensity of 65 foot-candles, uses an energetic developer and gets a slide with black lines on a perfectly clear background both for line diagrams and half-tone illustrations.

Drift of the *Sedov*

THE Northern Sea Route Administration of the U.S.S.R. is preparing for press a collection of articles and other material relating to the remarkable drift of the icebreaker *Sedov* in the Arctic, the crew of which was reported to have been taken off the icebound vessel by the icebreaker *Joseph Stalin* on January 13. The *Sedov* commenced her drift on October 23, 1937. The book being prepared for press tells the story of the *Sedov's* unprecedented drift. It contains articles by I. D. Papanin, head of the Northern Sea Route Administration and leader of the North Polar Expedition on the drifting icefloe of 1937–38, and by Prof. N. N. Zubov, and diaries of members of the *Sedov's* crew.

Clough Memorial Research Fund

The Clough Memorial Research Fund of the Edinburgh Geological Society was instituted in 1935 for the purpose of encouraging geological research in Scotland and the north of England; the north of England is defined as comprising the counties of Northumberland, Cumberland, Durham, Westmorland and Yorkshire. Under the terms of administration of the Fund, a sum of approximately £30 is available annually. Applications for grants are invited for the period April 1, 1939, to March 31, 1940. These applications should state the nature of the research to be undertaken and the amount of grant desired. Applications must be in the hands of the Secretary, Clough Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh, not later than March 1.

Royal College of Physicians: Lectures

The following lectures have been arranged by the Royal College of Physicians to be delivered at the College, Pall Mall East, London, at 2.30 p.m.: Mitchell Lecture (postponed from 1939), Dr. F. G. Chandler, "Some Observations on the Diagnosis and Treatment of Pulmonary Tuberculosis" (February 7); Milroy Lectures, Dr. R. E. Smith, "Acute Infectious Diseases at School" (February 13 and 15); Goulstonian Lectures, Dr. W. D. W. Brooks, "The Pathology and Treatment of Pulmonary Tuberculosis" (February 22, 27 and 29); Bradshaw Lecture (postponed from 1939), Dr. J. C. Spence, "On the Nature of Disease in Infancy" (March 7); Oliver-Sharpey Lectures, Prof. E. P. Cathcart, "The Mystery of Alimentation" (March 12 and 14); Croonian Lectures, Dr. George Graham, "Recent Advances in Diabetes Mellitus: Aetiology and Treatment" (May 16 and 21).

Royal Aeronautical Society: Lectures

Arrangements are being made by the Royal Aeronautical Society to resume part of the lecture programme which was postponed on the outbreak of war. It is hoped to arrange definitely for four or five lectures. The first one, on aircraft production, will be given by Mr. H. J. Pollard, on March 12 at 6.0 p.m., in the Institution of Electrical Engineers. Sir Alan Cobham and Mr. Marcus Langley have provisionally agreed to give a joint lecture on flight refuelling in the air; Mr. A. A. Hall on recent theoretical and experimental work on turbulence; Wing Commander T. R. Cave-Brown-Cave on noise and nuisance in aircraft, at dates to be fixed. The Wilbur Wright Lecture will be delivered at the end of May.

The Night Sky in February

During this month, the night shortens in the latitude of London by 1¾ hours. The moon is new on February 8 and full on February 23. Lunar conjunctions with the planets occur as follows with Venus on February 11d. 21h., with Jupiter on 12d. 14h., with Saturn on 14d. 3h., with Mars on 14d. 4h. It will be seen from these conjunctions that the bright planets are a striking feature in the evening skies, enhanced by the presence of the crescent moon. On February 13 at 8h., Mars which had overtaken Jupiter on January 7, is in conjunction with Saturn, while on February 20 at 22h., Venus and Jupiter are in conjunction. On February 28, Mercury is at greatest elongation (18° east) and should be visible low in the west after sunset, leading the train of five bright planets in addition to Uranus (stellar magnitude 6) in the constellation Aries. The planet Neptune, which transits about 2h. in mid-February, approaches the 8th magnitude star, B.D. + 3° 2549 (Lalande 22237) on February 14. The light variation of Algol (total variation mag. 2·2–mag. 3·5) is best seen about 1½ hours before and after the following epochs: February 8d. 4·5h., 11d. 1·3h., 13d. 22·1h. and 16d. 19·0h.

Announcements

Prof. Max Borst, professor of morbid anatomy at Munich, has been awarded the Goethe Medal for art and science on the occasion of his seventieth birthday for his work on cancer.

Sir Humphry Rolleston, chairman of the executive committee of the Imperial Cancer Research Fund since 1924, and Sir Thomas Dunhill, sergeant-surgeon to the King, were admitted to the honorary fellowship of the Royal College of Surgeons of England at a meeting of the Council on January 11. Sir Hugh Devine, president of the Royal Australasian College of Surgeons, has accepted the honorary fellowship subject to the condition of personal attendance at the College at some future date.

The number of births in France, which was 1,022,000 in 1876, fell to 750,000 in 1930 and 616,000 in 1939. For the last three years the number of deaths has exceeded the number of births by 14,000 annually.

Dr. Frans Verdoorn, formerly of Leyden, Holland, has now gone to the United States. Dr. Verdoorn controls the following publications: *Chronica Botanica*, New Series of Plant Science Books, "World List of Plant Science Institutions", "International Address Book of Plant Taxonomists", *Annales Bryologici* and other bryological publications. All communications concerning these should now be addressed to Dr. Frans Verdoorn, Chronica Botanica Co., c/o the Arnold Arboretum, Jamaica Plain, Mass., U.S.A.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

In the present circumstances, proofs of "letters" will not be submitted to correspondents outside Great Britain.

Notes on points in some of this week's letters appear on p. 151. Correspondents are invited to attach similar summaries to their communications.

The α-β Transformation of Quartz

As is well known, the ordinary form of quartz which has trigonal symmetry changes over reversibly to another form which has hexagonal symmetry at a temperature of 575° C. Though the transformation does not involve any radical reorganization of the internal architecture[1] of the crystal and takes place at a sharply defined temperature, it is nevertheless preceded over a considerable range of temperature (200°–575°) by a progressive change in the physical properties of 'low' quartz which prepares the way for a further sudden change, when the transition to 'high' quartz actually takes place. The thermal expansion coefficients, for example, gradually increase over this range of temperature, becoming practically infinite at the transition point and then suddenly dropping to small negative values[2]. Young's moduli in the same temperature range fall to rather low values at the transition point and then rise sharply to high figures[3]. The piezo-electric activity also undergoes notable changes[4,5].

In the hope of obtaining an insight into these remarkable phenomena, a careful study has been made of the spectrum of monochromatic light scattered in a quartz crystal at a series of temperatures ranging from that of liquid air to nearly the transition point. Significant changes are observed which are illustrated in the accompanying illustration, reproducing part of the spectrum excited by the 4358 A. radiation of the mercury arc. A fully exposed spectrum at room temperature indicates fourteen different normal modes of vibration of the crystal. At liquid air temperature, the three most intense lines correspond to the frequency shifts 132, 220 and 468 cm.$^{-1}$ and are all about equally sharp. As the crystal is heated over the temperature range 200°–530°, notable changes occur. The 220 cm.$^{-1}$ line (marked with an arrow in the reproduction) behaves in an exceptional way, spreading out greatly towards the exciting line and becoming a weak diffuse band as the transition temperature is approached. On the other hand, the other intense lines having both larger and smaller frequency shifts continue to be easily visible, though appreciably broadened and displaced.

The behaviour of the 220 cm.$^{-1}$ line clearly indicates that the binding forces which determine the frequency of the corresponding mode of vibration of the crystal lattices diminish rapidly with rising temperature. It appears therefore reasonable to infer that the increasing excitation of this particular mode of vibration with rising temperature and the deformations of the atomic arrangement resulting therefrom are in a special measure responsible for the remarkable changes in the properties of the crystal already mentioned, as well as for inducing the transformation from the α to the β form.

First Benedicks Effect in Gas-free Mercury, as Influenced by the Mean Temperature

IN a previous letter[1] we have shown that, in mercury carefully freed from gas ions, the First Benedicks effect exists with a positive sign, whereas in the presence of gas ions the effect had shown a negative sign. The influence of gas ions actually seems thoroughly to modify the thermo-electric properties of some metals.

In view of the fundamental character of this influence, the experiments on mercury have now been repeated, using a strangulation apparatus made of silica, with a new heating arrangement (hot and cold flowing oil), and also a photographic registration method. Fig. 1 exemplifies the registrations finally obtained: in the upper parts are to be seen the relay-amplified deflections of the galvanometer, showing small oscillations due to Brownian movement; below, the corresponding temperature registrations.

The new observations were found entirely to confirm the positive character of the effect in gas-free mercury. They further reveal a new, important fact.

From a quantitative point of view, the effect is determined by the formula

$$u = K \cdot \frac{3}{\Delta t} \qquad (1)$$

The parameter K, depending on the metal and, to a certain extent, on the apparatus used (here No. 20), and hence now designated as K_{20}, has been calculated from the observations, using (1), and plotted as ordinates in Fig. 2, where abscissæ are the mean temperatures t_{med}.

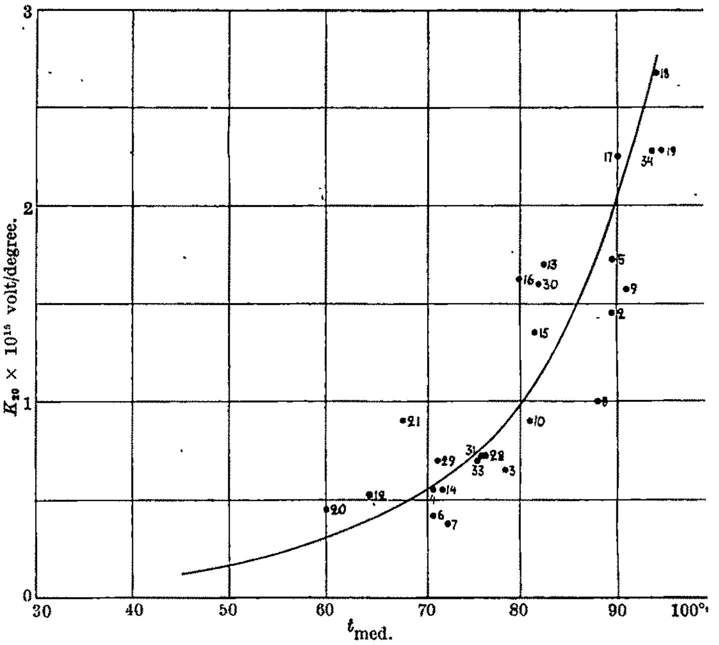

Fig. 2.

FIRST BENEDICKS EFFECT IN MERCURY.

It will be seen that the effect varies with the temperature, *increasing in a strongly accelerated way*.

It is interesting that this increase, with increasing temperature, of the First Benedicks effect appears to be just the same as that which has been discovered earlier for the reversed effect, the Second Benedicks effect[2], and which presents a striking similarity to the well-known Richardson formula, valid for electron emission from glowing metals. It actually appears plausible that the emission of electrons along a steep temperature gradient in the metal may follow the same law as the emission into vacuum.

Magnetic Anisotropy of Diphenyldiacetylene

E. H. WIEBENGA has recently determined the crystal structure of diphenyldiacetylene[1] $(C_6H_5).C{:}C.C{:}C.(C_6H_5)$. The molecule is plane, with a straight carbon chain, the length of the molecule making angles of approximately 48°, 52°, 78° with the *a,b,c* axes of the monoclinic unit cell. (By inadvertence, the complements of the first two angles were given in Dr. Wiebenga's letter in NATURE. He has since very kindly sent me the exact direction cosines determined by means of a Fourier analysis and has also provided me with some beautiful crystals for this investigation.)

The magnetic anisotropy of the crystals, weighing about 4 mgm. each, density 1·170 gm./c.c. at 20° C., was determined by Krishnan's second method in a field of some 7,000 oersted. The minimum diamagnetic susceptibility was determined by the flotation method. The principal crystal susceptibilities are $\chi_1 = -93{\cdot}8 \times 10^{-6} (\pm 0{\cdot}5)$, $\chi_2 = -188{\cdot}0 \times 10^{-6}$, $\chi_3 = -109{\cdot}6 \times 10^{-6}$, $\psi = -88{\cdot}5°$. Hence the mean susceptibility is $-130 \cdot 5 \times 10^{-6}$, as compared with $-115 \cdot 9$ for tolane and $-102 \cdot 9$ for diphenyl. Pascal's rules would give $\chi = -129 \cdot 7$ for diphenyldiacetylene: he himself found the value $-129 \cdot 3$ (corr.). The principal susceptibilities of a single molecule, deduced from the above data and the molecular direction cosines, are $K_L = -109 \cdot 4$, $K_M = -75 \cdot 3$, $K_N = -206 \cdot 7 \times 10^{-6}$.

Comparing these with the corresponding values for tolane[2], $K_L = -81 \cdot 5$, $K_M = -67 \cdot 8$, $K_N = -198 \cdot 5 \times 10^{-6}$, it will be seen that there is an abnormal increase of susceptibility along the carbon chain axis, indicating a concentration of electron density normal to that axis. This is in sharp contrast to the behaviour of chains of conjugated double bonds, for which the increase of susceptibility is always normal to the plane of the molecule, indicating a concentration of electron density in that plane. An exact Fourier analysis of the structure of diphenyl is very desirable, in order to extend the comparison from tolane to diphenyl.

Crystal Structure of Phosphorus Pentachloride

ALTHOUGH much work has been done on the molecular structure of phosphorus pentachloride, no crystal structure determination of this important substance has previously been made, presumably owing to experimental difficulties. In our separate laboratories, independent X-ray diffraction experiments have given the following results: Crystal system tetragonal, approximate cell dimensions $a_0 = 9 \cdot 2$, $c_0 = 7 \cdot 4$ A., density *circa* 2·0 gm./c.c., 4 molecules per unit cell, space group $P4/n$.

This information is sufficient to determine the constitution of the compound. Consideration of the space group symmetry and the available space shows that it is impossible to form a structure containing PCl_5 molecules of any configuration. For similar reasons the constitution $[PCl_4]^+Cl^-$ may also be rejected. An ionic structure containing tetrahedral $[PCl_4]^+$ and octahedral $[PCl_6]^-$ groups completely satisfies the requirements. For a unit cell with origin as in the "Internationale Tabellen zur Bestimmung von Kristallstrukturen", the centres of $[PCl_4]$ groups are at 000, $\frac{1}{2}\frac{1}{2}0$, and those of $[PCl_6]$ at $0\frac{1}{2}z$, $\frac{1}{2}0z$, $z \approx \frac{5}{8}$. Preliminary Fourier analyses have confirmed these conclusions, and further details of the structure will be given later.

Degeneracy and Dissociation Constants

THE importance of degeneracy in enhancing the stability of radicals such as triphenylmethyl has been emphasized by many authors; for example, Pauling and Wheland[1], Ingold[2], etc. This being so, it is strange that no relations have been suggested between complexity of degeneracy (which we may define in terms of the number of possible resonating structures) and dissociation constants of series of related acids and bases. It is probable that simple relations will be discovered only in series where the inductive effects of substituent groups are negligible, or can be eliminated.

Consider the series of acids, methyl alcohol (K of the order 10^{-16}), acetic acid ($K = 1 \cdot 75 \times 10^{-5}$), phenylacetic acid ($K = 4 \cdot 88 \times 10^{-5}$), and diphenylacetic acid ($K = 11 \cdot 5 \times 10^{-5}$). (All K values, which are thermodynamic ones, have been taken from Dippy's recent article[3].) Now the inductive effect of the $C{=}O$ group moment fails to account for the enormous increase in strength (the ratio being 10^9) when we proceed from methyl alcohol to acetic acid, for chloracetic acid is only 100 times as strong as acetic acid. However, two resonating structures ($n = 2$) are possible for the acetic acid molecule ion, and the energy of resonance effects stabilization.

In the same way, the inductive effect of the phenyl group, which must be very small, will not account quantitatively for the acid strengths of phenylacetic and diphenylacetic acids. Even if we assumed (wrongly) that the increase in K in going from acetic to phenylacetic acid is due to an electrical inductive effect of the phenyl group generally designated as $-I$, the strength of diphenylacetic acid is definitely larger than what we should deduce on that hypothesis. It seems fairly obvious that the enhanced stability of the phenylacetic and diphenylacetic acid ions is due to an increase in the number of resonance

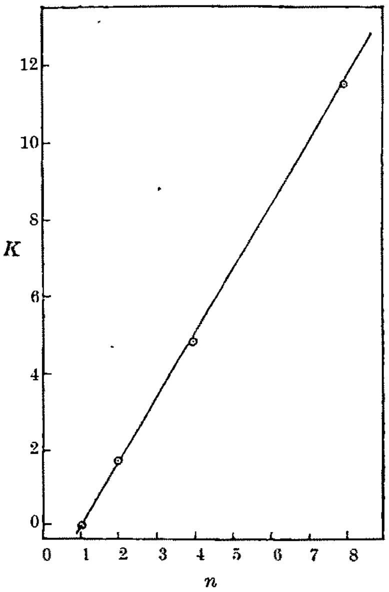

Fig. 1

possibilities, for it is easy to show that $n = 4$ and $n = 8$ respectively, and a linear relation (see Fig. 1) exists between K and n for the three acids. A fourth point for the line is provided if we assume that a non-resonating 'acetic acid' ($n = 1$) would have a strength of about 10^{-13} or zero on our scale. (Dippy and Lewis[4] have already identified the apparent intrinsic attraction for electrons exhibited by the phenyl group with its unsaturated character.) The dissociation constant of triphenylacetic acid in water has not been measured on account of solubility difficulties. Its strength may be predicted by extrapolation to $n = 16$ as $K = 25 \times 10^{-6}$.

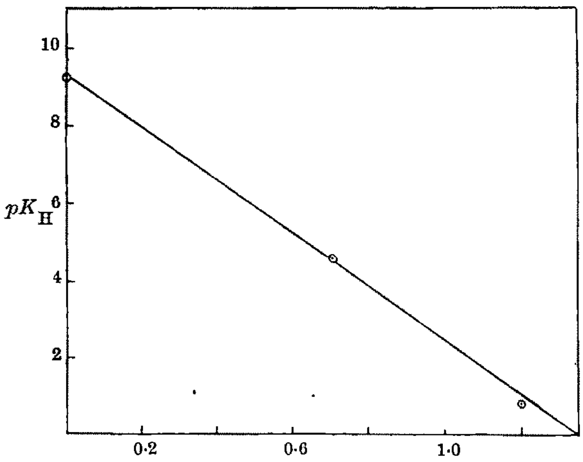

Fig. 2

In the case of a series of related bases, ammonia ($pK_H = 9{\cdot}27$, $n = 1$), aniline ($pK_H = 4{\cdot}62$, $n = 5$), diphenylamine ($pK_H = 0{\cdot}85$, $n = 16$), and triphenylamine ($pK_H = 0$, $n \gg 30$), it is the unionized molecule which is preferentially stabilized by the resonance energy. (Unlike the ion, the unionized molecule has a lone pair of electrons.) In Fig. 2 a plot is shown of pK_H against log n, and again a linear relation is found. This method of plotting is more convenient on account of the large difference in basicities. Triphenylamine has zero pK_H as predicted by the relation.

These methods of plotting are really equivalent to plotting the dissociation constant against the total resonance energy involved as n is increased. Each additional structure contributes equally to the actual hybrid state of the molecule. An examination of the dissociation constants of related series of compounds (and activation energies when reacting) will probably yield just as much valuable information about the relative importance of structures as heat data, internuclear distances, and electric dipole moments have already done.

Predaceous Phycomycetes from Cotswold Leaf-Mould

DRECHSLER[1] has described in America more than a dozen species of Phycomycetes parasitic on nematodes and terricolous amœbæ. These he places in the Zoopagaceæ, a family of uncertain taxonomy, related to the Mucorales. To the best of my belief, no members of this family have been recorded in Europe, with the possible exception of some organisms described by Penard[2] in 1913, and placed by him, probably incorrectly, in the Saprolegniaceæ. It may be of interest, therefore, to record the finding of four species of Zoopagaceæ in plate cultures inoculated with leaf-mould from wooded areas in the Cotswolds.

Cochlonema verrucosum, Drechsl., is endoparasitic in soil amœbæ. Infection begins by a conidium becoming attached to the pellicle of an amœba, and sending out a germ tube which enters the host and forms a mycelium within the endoplasm. This mycelium is thalloid, at first sub-spherical, becoming sausage-shaped, and finally twisted in a close spiral, usually of about one and a half turns. The diameter of a mature hypa is about 6 μ. Growth takes place at the expense of the host's protoplasm; but the host remains active until the parasite reaches an advanced stage. Multiple infection is usual. Finally, the host becomes immobilized and dies. Reproduction then occurs by means of chains of aerial conidia, borne on conidiophores usually 1·5 μ in diameter. The conidia are fusiform, 7 μ long and 1·5 μ in greatest diameter.

Sexual reproduction takes place by the union outside the host of slightly unequal gametangia. Zygospores are usually formed between gametangia from different mycelia; they are 10 μ in diameter and are enclosed in a thick wall, bearing on its outer surface twenty or more bullate protuberances.

Cochlonema dolichosporium, Drechsl., resembles *C. verrucosum* in size and habit, and was found attacking *Amœba similis*, Greef. It is characterized by its chains of elongate conidia, which have an average length of 20 μ and greatest diameter 1·5 μ. Like the conidia of *C. verrucosum*, their external wall is considerably sculptured. Zygospores of this species were not observed.

Stylopage haplœ, Drechsl., forms a sparsely branching mycelium, the branching being roughly at right angles. The hyphæ are non-septate, 1·2 μ–1·5 μ in diameter, and the cytoplasm is considerably vacuolated. Amœbæ become attached to the hyphæ, which send out dichotomously branching haustoria into the endoplasm of the host; the host eventually becomes completely absorbed, leaving only the shrivelled pellicle attached to the haustorium. Reproduction is by clavate conidia, 15 μ long and 2 μ–2·2 μ wide at the broadest part, borne singly on erect conidiophores 20 μ–30 μ long. Zygospores were not observed.

Stylopage hadra, Drechsl., resembles *S. haplœ* in habit, but is much larger, the rather straight, non-septate hyphæ measuring 4 μ–5 μ in diameter. This species catches nematodes, which become attached to the hyphæ, probably by means of some sticky substance. A bulbous lateral protuberance is formed on the hypha at the point of attachment of the nematode, and, from this, hyphæ grow out and ramify inside the host, absorbing its contents. Ultimately, only the withered integument of the nematode is left, attached to the bulb. Reproduction is by ovoid conidia, 25 μ–35 μ long and 15 μ–20 μ in greatest diameter, formed terminally on aerial conidiophores which may, by repeated growth, bear several conidia. Zygospores were not observed.

Further details of these and other related fungi will be the subject of a paper to be published later.

I should like to express my thanks to Dr. B. Barnes for much valuable advice and help, and also to Dr. C. G. C. Chesters, of the University of Birmingham, for kindly allowing me to use his laboratory.

Radium Treatment

Reference is made in Nature of December 9, 1939, p. 973, to a paper (*J. Roy. Soc. Arts*, Dec. 8, 1939) entitled "The Penetration of Rays through the Skin, and Radiant Energy for the Treatment of Wounds", in which I express the view that we would be little the worse off if all the radium now buried in deep holes for security from bombing remained there, and states that the Cancer Act is Great Britain's reply to the question whether monetary influence determines the practice of radium therapy in Great Britain.

Radium, a destroyer of living cells in active division, cannot be used to attack cancer without also damaging living normal cells of the circulating blood, etc. It can only be used for accessible cancers in the skin or surfaces of the body, which can be removed in nearly all cases by the knife or the diathermy needle of the surgeon; and these last do not cause necrosis and incurable neuralgias, which have often followed the use of radium. Deaths due to leucopænia have resulted from vain attempts to cure deep cancers by the use of radium in bombs. I can instance the damage done by radium by a case now attending the St. John Clinic and Institute of Physical Medicine; radium treatment of a small epithelioma in the skin on the side of the skull resulted in necrosis of the bone, probably incurable, in an area the size of the top of a sherry glass.

Loss of well-being and an incurable neuralgia were recorded by Mr. Furnival, the late distinguished surgeon, who died not long after radium treatment, in his case of cancer of the throat. Such an intolerable neuralgia was suffered by a relative of mine through treatment of a cancer of the root of the tongue, and he also died of a recurrence; and I have heard of many other such cases. There are good clinicians who hold the view that the use of radium favours the spread of metastases. Radium is popular because it can be used instead of the knife, which people dread, and therefore doctors use it.

X-ray apparatus is now available which operates at a million volts or more, so that radiations approaching those of radium are produced. The dosage of radium is controlled by time and filtration; that of X-rays can be further controlled in wave-length and intensity. Radium may be chosen as more convenient for application in such a place as the larynx.

Both radium and X-rays can produce, not only necrosis, but also cancer, and Sir Norman Walker considers that the use of X-rays for lupus should be abandoned. I know of an excellent laboratory servant who, only by continued observation and treatment, is kept, so far, free from cancer resulting from scars due to X-ray treatment of lupus of the face.

We know that death has resulted in several workers who licked the paint off brushes when applying luminous, radioactive paint to watch dials, and cancer has resulted from a radium tube being left in the body. Those who mine radium-bearing ore die generally from cancer of the lung.

The *Lancet* (Dec. 23, 1939) says, "to ensure that radiation treatment is in charge of really competent workers, and to give opportunities for training therapists, a high degree of centralisation will be more effective than the creation of individual treatments units". "To use both radium and X-rays to the best advantage some surgical training and a good grasp of radiation physics are needed, and for the purpose of the Act clinical knowledge of cancer in all its manifestations as well".

While vast sums have been spent on radium, numbers of poor people have to die, unrelieved, of cancer, in their homes. The pressing needs are to spread knowledge, secure prevention where possible, and very early diagnosis, allowing a hopeful removal by the knife or diathermy needle, which can be used by surgeons everywhere, the use of radium or X-rays being reserved for one or two places in the body where surgical operation is very difficult, and to be used by specialists as the *Lancet* suggests. There is no trustworthy evidence that radium in weak doses has any beneficial action.

"Evidence for Transformation of Mesotrons into Electrons"

In our note under this title published in Nature of January 20, p. 102, we stated in reference to the cloud photographs reproduced that the faint electron track *FG*, leaving the end of the mesotron track "is comparable in density with the tracks of other fast particles" in the photograph. This was the case in the original negatives, in the prints submitted for publication, and in the first proofs received, except that in the latter all the tracks were fainter. However, in Fig. 1 of the published note, the track *FG* appears much more pronounced and thicker than in the original prints—being quite obvious while other electron tracks in the same region are scarcely detectable. A new set of blocks was made for the final publication; the Editors assure us that no part of Fig. 1 received preferential treatment and suggest that the great intensity of the track concerned may have arisen from a very favourable inclination of its direction with the mesh of the screen used in reproduction.

We take this opportunity of pointing out that the arrow pointing to the δ-track at *E* in Fig. 4 should be about 2 mm. lower.

G. E. Roberts.

"Victorian Socialism"

IN a very interesting essay entitled "Victorian Socialism" which Dean Inge contributed to NATURE of January 13 as if it were a review of my "New World Order", he makes certain statements for which I think it is reasonable to demand documentation. He says that the Nationalists (that is, the Franco rebels) took arms "against those devils in human shape, the Spanish Reds", etc. But is it not a matter of fact and common knowledge that Franco led his Moors against a Liberal Republican Government which had recently suppressed a very dangerous anarchist-socialist rising? (see Sender's "Seven Red Sundays", translated by Sir Peter Chalmers Mitchell, F.R.S.). Further, he gives an explicit account of abominable atrocities committed at Ronda. But surely in NATURE we want something more than an unnamed "American eye-witness" for statements of that sort. Who was he? How can we check his testimony? Is he available for cross-examination? Then about that three hundred thousand men and women "butchered under orders from Moscow". Is there a single respectable scrap of evidence for any part of that statement. Which we may find quoted presently as a statement made in NATURE.

H. G. WELLS.

13 Hanover Terrace,
Regent's Park, N.W.1.

I HAVE made a careful study of the Spanish horrors, and have accepted none but well-documented evidence. The Ronda story is from a book by Arthur Bryant. I could have found several equally dreadful examples by Spanish eye-witnesses, but some of them I did not care to keep on my shelves. The estimate of 300,000 victims is official; some have put the number much higher. Krivitsky's "I Was Stalin's Agent" is most illuminating; for example, p. 120: "The Ogpu had done a brilliant piece of work. In Dec. 1936 the terror was sweeping Madrid, Barcelona, and Valencia. The Ogpu . . . carried out assassinations and kidnappings. . . . The Soviet Union had a grip on Loyalist Spain, as if it were already a Soviet possession." This book may be enough for my friend Mr. Wells, who is a very honest man.

Scientific Workers and the Armed Forces

THE announcement published in NATURE of January 13, p. 61, "that the operation of the Schedule of Reserved Occupations is being relaxed to enable men at or above the age of reservation in scientific occupations to volunteer in approved cases for service in the Forces" calls for certain comments.

The increase in unemployment among scientists, particularly chemists and biologists, which may be the cause of this relaxation of the schedule and is the cause of much concern in this Association, is largely due to the reduction of 'civilian' research and the impossibility of absorbing all these scientists into direct war research. Through the somewhat uneven incidence of the economy campaign, many lines of research are already in jeopardy; it is only necessary to mention the example of food research. In the leading article of the same issue of NATURE, suggestions are made for new lines of research directly related to the needs of the population in war-time. In addition to such lines of work, there can also be suggested scientific work which is of less direct importance to a country at war but should be inaugurated at once so that its results may be available when required. The most obvious example of this kind of work is research on problems of substitute materials, in which Germany is at present probably ahead of Great Britain.

The fact that chemists and other scientists are now allowed to enlist in the Forces in other than their professional capacity suggests that there is a shortsightedness in the scientific direction of the country.

Points from Foregoing Letters

THE ordinary form of quartz with trigonal symmetry changes at 575° to a form with hexagonal symmetry, the change being preceded by a progressive change of physical properties. Sir C. V. Raman and T. M. K. Nedungadi find an explanation for these effects as a result of an examination of the scattering of monochromatic light in quartz at various temperatures up to the transition point.

The First Benedicks effect (passage of an electron current in a metal subjected to a temperature gradient) in gas-free mercury has been re-examined by C. Benedicks and P. Sederholm. They find that the effect increases rapidly with increase of the mean temperature of the metal, the law of increase being similar to that for the emission of electrons into a vacuum (Richardson's law).

The principal diamagnetic susceptibilities of the diphenyldiacetylene molecule have been measured by K. Lonsdale. A concentration of electron density normal to the carbon chain axis is indicated by a comparison of the results with those previously found for tolane.

Independent X-ray crystallographic examinations of phosphorus pentachloride by H. M. Powell and D. Clark in Oxford and by A. F. Wells in Cambridge have established the constitution of this compound in the solid state. The structure contains tetrahedral $[PCl_4]$ and octahedral $[PCl_6]$ groups.

H. O. Jenkins finds that linear relations exist between the complexity of degeneracy, defined in terms of the number of possible resonating structures, and the dissociation constants of series of related acids and bases.

C. L. Duddington describes four species of predaceous Phycomycetes, belonging to the Zoopagaceæ, found in leaf-mould from the Cotswolds.

RESEARCH ITEMS

A Neolithic Trackway

A possible Neolithic trackway across the Cotswolds has been traced by Miss C. A. Simpson and Miss Clifford and is described by them in *Geography* of December. It extends north-eastward from Bisley by Duntisbourne, Chedworth and Northleach to the edge of the low and swampy ground of the Windrush valley west of Bourton-on-the-Water, where it swings north and then west towards Nutgrove and beyond. In Neolithic times the limestone plateau of the Cotswolds was probably covered by low scrub and there were few trees. The valleys, however, were mainly floored by clay and sand, and afforded marshes which restricted the crossing places. On the plateau the trackway is less easy to trace, for it was probably less well defined. Long barrows in conspicuous places were probably landmarks and also the objectives of some of the travellers. Flints and stone weapons are also useful clues. On the valley sides, however, the track is frequently sunk either in clay or limestone outcrops. Projecting spurs of firmer ground often lead to the river crossing. In some places the route follows a line of present road, but more often it is marked, if marked at all, by a narrow lane, a bridle path or even a double line of hedge. The authors' discussion of the evidence to be sought in tracing the trackway has many useful indications for such work.

Feet of Melanesians and Europeans

A study of the footprints of sixty-five natives of the Solomon Islands by Clifford S. James, of the Melanesian Mission Hospital, Malaita (*Lancet*, 237; Dec. 30, 1939), affords material for contrast with those of Europeans. The longitudinal arch exists in both Melanesians and Europeans and is a definite fixed part of the anatomy. This is contrary to the view recently expressed that there is no fixed arch "in primitive races who have never worn boots or shoes". As regards differences between the foot of a European and the Solomon Islander, that of the latter is more massive and broader, especially in the male, lacking the 'elegance' (usually pathological) of the European foot. The toes of a native are straight, lie parallel with the ground, and are spread out so that the inner and outer borders of the foot are two straight lines. Occasionally the great toe is abducted so that the inner border of the foot is concave medially, and the other foot has to 'step over' the great toe. A native in walking uses his toes more than does a European; and the final push-off is from the toes. The most obvious difference in the two footprints is that the European's foot is always turned outwards to various degrees when walking, while that of the native has its inner border pointing straight ahead with slight variations one way or another. The female foot being less massive than the male, its mobility and pliability are most noticeable, especially as shown in the way the foot spreads out over the ground when the body weight is put on to it. The print of a European aged 5½ years who had never worn shoes, when superimposed on that of a native, showed striking similarities. Flat-foot does not occur among the natives.

Biological Control of a Fungus Disease

The honey fungus, *Armillaria mellea*, is of world-wide distribution. It is widespread upon forest trees in Great Britain, and is very destructive to tea plantations in Nyasaland. R. Leach has made some interesting experiments on biological control of the disease in the last-mentioned venue (*Trans. Brit. Mycol. Soc.*, 23, Pt. 4; December 1939). Forest land has to be cleared of trees before tea bushes can be planted. The fungus attacks roots left in the soil, and later can transfer its parasitism to the economically valuable bushes, with disastrous results. Cutting a ring of bark from trees some time before they are felled, however, depletes the roots of carbohydrates, and thereby deprives *A. mellea* of an acceptable substrate. It does, in fact, effect such a large edaphic change that other organisms establish themselves in the decaying roots, and exclude the parasite, which can even be prevented from spreading by felling a belt of bark-ringed trees.

New Descriptions of Agarics

The Aviemore foray of the British Mycological Society yielded some interesting new records of Agaricaceous fungi, mostly of the genus Russula, which are described by A. A. Pearson in the Society's *Transactions* (23, Pt. 4; December 1939). Several of the species, as *R. rosea*, *R. vinosa and R. gracillima*, have occurred in other countries, but a new species, *R. scotica*, is also delineated. This is similar to *R. cremeo-avellanea*, which is found in the Pyrenees; but differs in the non-reticulated spore and absence of cystidia on the pileus.

Shoot Wilt of *Prunus triloba*

The fungus *Botrytis cinerea* is often thought of as a saprophyte, but it has been found to show active parasitism upon some plants. W. C. Moore has recently described a shoot wilt disease of *Prunus triloba*, caused by this organism (*Trans. Brit. Mycol. Soc.*, 23, Pt. 4; December 1939). New shoots wilted suddenly shortly after flowering, the bark died and it became brown. A wilted flower cluster was always associated with such shoots, and the disease appeared most severely when the weather was wet before the end of May. Pathogenicity of the organism mentioned was proved by isolation and re-inoculation.

Theory of Differential Periodicity

G. F. Sleggs (*Growth*, 3, 173–179; 1939) puts forward a theory of gene structure and development of the organism which is based on the interactions of protein lattices. If one projects all the genes, cytoplasm and other intergenic material in every cell of the organism into one structure, the author considers that the genes are equivalent to a stack of horizontal lattices differing in spatial period. Growth then is basically a process of lateral extension of the vertical strips of the lattice system. The minimum effective fragment will be a chain of the mesh, for example, the spireme. The equipotentiality of the system lies in the fact that any vertical strip can regenerate the whole differential pattern of the lattice stack. All genes are thought to be similar, differing only in spatial arrangement. The differential in the amino-acid frequency is believed to result from gene rotation. On this view it is possible to account for differential mitosis, the relationship between cytoplasmic and other intergenic material and growth phenomena, and evolutionary trends by the conception of rotations in a protein lattice stack.

Genetics of *Primula kewensis*

MOST interesting facts have resulted from the examination of *Primula kewensis* by M. Upcott (*J. Genetics*, 39, 79–100 ; 1939). There are two types of tetraploids known ; the first resulted from the doubling of chromosomes in branches of the diploid cross *P. floribunda* × *P. verticillata* ; the second arose from backcrossing the first type to *P. floribunda*. The first contains two complements each of *floribunda* and of *verticillata* chromosomes while the second contains three sets of *floribunda* to one of *verticillata*. The diploid, sterile *P. kewensis* forms bivalents and one to two pairs of univalents. The sterility of the hybrid is not due to difficulties of chromosome pairing. Evidence has been provided of the manner in which gametes with less than the normal reduced number of chromosomes may occur. 8 per cent of the pollen grain division of the tetraploid *P. kewensis* showed "double plates" ; that is, either several chromosomes lie off the main divisional plate and form a secondary plate on their own or the mitotic spindle is curved. Should the chromosomes forming the secondary plate be a compatible complement, say $n = 9$, there is a chance of gamete production with 9 chromosomes in place of the normal 18 from tetraploid *P. kewensis*. It is shown that tetraploids have consistently a lower chiasma frequency than the related diploids.

Quantitative Characters

LEROY POWERS (*J. Genetics*, 39, 139–170 ; 1939) describes an experiment in *Lycopersicum esculentum* and *L. pimpinellifolium*, in which the analysis of variance is applied to the study of the inheritance of the number of locules and the size of fruit. He shows how the analysis of variance may be usefully applied to genetical problems. Variances were heterogeneous for "between genotypes" and for "between generations" and, to some extent, for "between sampling blocks". The variability of the variances is a function of genotypes. There would appear to be at least three pairs of allelomorphs involved in the determination of both number of locules and size of fruits. Their interactions are geometrically cumulative, but it is shown that interactions between pairs of allelomorphs are different from those within pairs, and proper experimental methods should be adopted to keep these differences distinct.

Greenland Ice Sheet

THE advance and retreat of valley glaciers is frequently cyclic and not progressive in either direction. It is often more dependent on local topography than on changes in climate. In recent observations in north-west Greenland ("Contributions to the Glaciology of North-West Greenland", *Meddelelser om Grønland*, 125, No. 3), J. W. Wright shows that advance and retreat have occurred in the Moltke Glacier this century, but agrees that other evidence than that of valley glaciers is required for movements of the ice cap. This evidence he believes he has found, pointing to a recent retreat of the ice cap in Inglefield Land. Several new nunataks have appeared during the last few years ; their appearance is vouched for by Eskimos. A long narrow lake, on the ice-free land, but adjoining the ice cap, has lately undergone a drop in level as shown by the former strand line ; presumably its outlet until recently was dammed by a tongue of the ice which has now disappeared. Further evidence of retreat is the occurrence along the edge of the ice cap of rock not yet bearing the normal covering of lichen. Lastly, Mr. Wright cites the disappearance during the last ten years of an ice cap covering a small island and the melting of the snow drifts that were perennial on the slopes east of Thule.

Microseisms and Transmission of Atmospheric Disturbances

As the result of the mathematical examination of an ideal case in which atmospheric disturbance is transmitted through a layer outside or within which a steady air current is blowing, Katsutada Sezawa and Kiyoshi Kanai (*Bull. Earthquake Res. Inst. Tokyo Imp. Univ.*, 17, Pt. 3, 548–557 ; 1939) arrive at some interesting conclusions. When it is possible for the disturbance to be transmitted through such a layer, the amplitude of the waves becomes a maximum for a certain range of periods, which condition would be one of the important causes of microseismic oscillation. It is possible for there to be two kinds of waves transmitted along this ideal atmospheric layer ; one has a velocity comparable with that of sound waves and the other has a velocity of the order of a small fraction of the velocity of sound waves. Waves of both these kinds are transmitted only in the same or the reverse direction of the wind. The condition determining such a direction of wave transmission depends on wind velocities both in the upper and lower atmospheres. It is pointed out that microbarometric records register an aggregate of local disturbances of smaller periods, particularly those of a gravitational nature, and it may not be possible to pick out the main oscillations of smaller periods that occur in a relatively large area. For this reason it may not be possible to show any correspondence between microbarometric oscillations and microseismic oscillations.

Use of Monochromatic Image in the Spectrohelioscope

M. A. ELLISON has published a paper on the formation of the monochromatic image in a spectrohelioscope (*J. Brit. Astro. Assoc.*, 50, 2 ; 1940) which will prove very useful to solar observers. As it deals with various details too numerous to summarize in a short space, those who are interested in the subject are referred to the original paper. Briefly, Ellison considers the three possible arrangements for the 'scanning' and 'viewing' slits, and points out the advantages as well as the disadvantages of each one. He refers specially to the convenience when the slits are placed side by side, about five inches apart and parallel to one another, a method adopted by F. J. Sellers, director of the Solar Section of the British Astronomical Association. A description of the apparatus has already appeared (*J. Brit. Astro. Assoc.*, 48, 6 ; 1938) and Ellison has used a similar apparatus with his spectroheliοscope, the results being very satisfactory. A short account is given of the Anderson prism device, which is an alternative to the slit mechanism and was applied by Hale to the spectrohelioscope.

FURTHER APPLICATIONS OF THE PHOTOGRAPHIC METHOD IN NUCLEAR PHYSICS

By Dr. C. F. Powell,

The Wills Physical Laboratory, University of Bristol

In a letter published in Nature of July 15, 1939, p. 115, attention was directed to the fact that the photographic plate provides a very powerful instrument for investigations depending on the detection and measurement of the energy of heavy charged particles, notably protons, and of neutrons. It was shown that the method, when applied to determining the energies of the neutrons liberated from the light elements under deuteron bombardment, yields essentially the same information as that provided by the expansion chamber. The photographic method has, however, marked advantages over the expansion chamber, which were described.

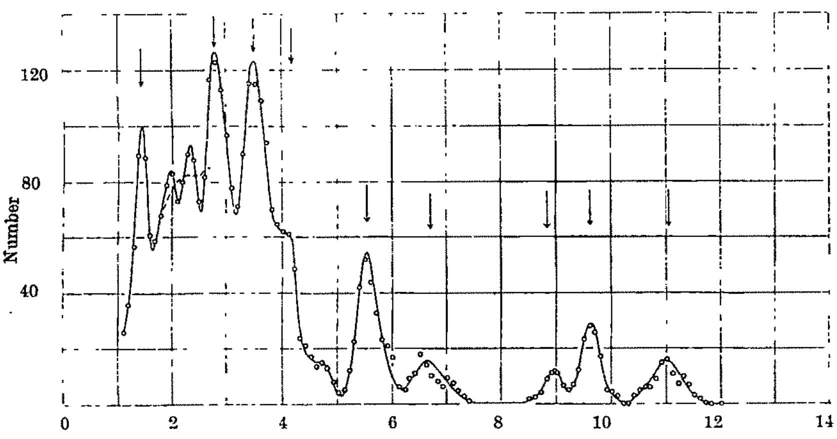

Fig. 1.

Forward neutrons from F + D at 900 kv.
Number per 200 kv. range plotted for every 100 kv. Peaks statistically justified are shown by arrows. Two tracks were also observed, at 13·2 and 13·6 eMv. respectively, which suggest slight boron contamination of the target.

The first experiments were made on neutrons of which the energy spectrum had already been investigated. It was, therefore, of importance to apply the method to an investigation in which previous work could not serve as a guide able to prejudice the experimental observations. Adequate checks were applied in the previous work and it is believed that the results are free from this objection, but nevertheless an independent experiment was desirable. Through the courtesy of Prof. J. D. Cockcroft and Mr. P. I. Dee, it was possible to examine the neutrons from fluorine under bombardment with 900 kv. deuterons from the Cambridge one million-volt generator. The results are shown in Fig. 1, and are taken from measurements on 1,700 tracks contained in 4 sq. cm. of an Ilford half-tone plate of which the emulsion was 100 μ thick. The results were obtained with an exposure of two hours with 30 microamperes in the resolved deuteron beam, the plate being at a distance of about 10 cm. from the target and in a position to detect forward neutrons. The measurements of the tracks were made by a single observer in about sixty working hours. We understand that the same spectrum has been investigated by Dr. T. W. Bonner using the expansion chamber, and that his results will be published shortly. We have not seen his results, and it will thus be possible to make a completely independent check on the validity of the photographic method. Two tracks of 13·4 eMv. protons suggest boron contamination of the target, and this may be responsible for the peaks at 4·3 and 9·0 eMv. Further work will be necessary to decide this point.

It was suggested in the previous letter that the photographic method is equivalent to a continuously sensitive expansion chamber. We believe it possible to press the analogy further in the sense that the spatial orientation of a track in the emulsion can be determined. With objectives of high aperture, the depth of focus is so small that it is possible to determine the depth of individual grains in the emulsion with a high degree of precision, and hence the angle of inclination of a track to the plane of the plate. In addition, the direction of the projection of the track on the plane of the plate can be measured to within a quarter of a degree and the direction in space thus defined. We have examined the distribution in angle of the protons ejected by the neutrons from boron under deuteron bombardment as they pass though the plate.

We and other observers have shown that the high-energy neutrons from this reaction fall into four groups with energies of approximately 4, 6, 8·7 and 13·3 eMv. when the bombarding deuterons have an energy of 600 ekv. If a neutron of energy E_0 is scattered by a proton, the energy acquired by the proton, if projected at an angle β with the direction of the incident neutrons, is $E_0 \cos^2\beta$. If we measure the range of protons projected in a photographic plate by the boron neutrons, we should therefore expect the ranges of the observed tracks to be distributed, according to the angle β, in a way corresponding to this energy equation. We should expect the points to lie, not on four lines, but within four bands as a consequence of:

(a) the straggling of the protons,

(b) the uncertainty of ±2° in the direction of the neutrons entering the plate, owing to the width of the deuteron beam striking the target, and

(c) an uncertainty of ±1° in the determination of β.

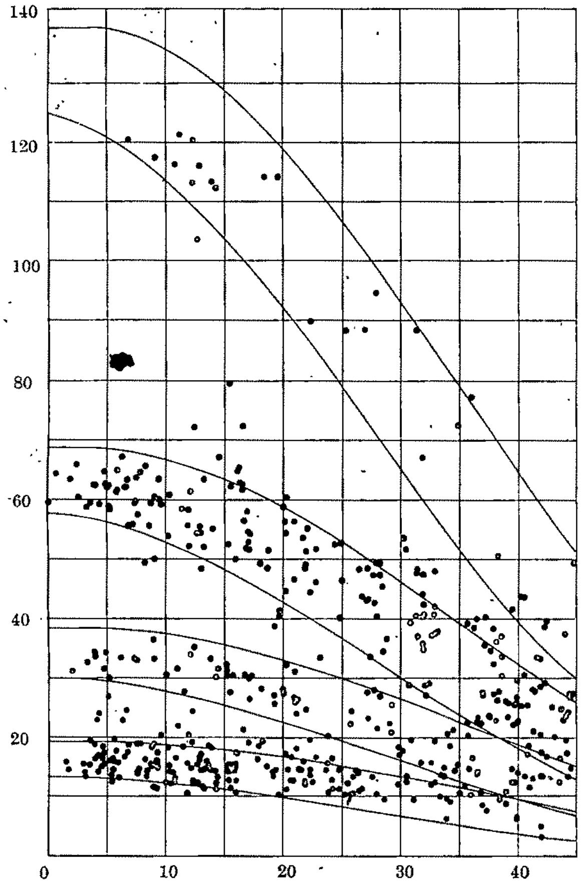

Fig. 2.

DISTRIBUTION OF RANGE WITH ANGLE FOR 500 PROTON TRACKS SCATTERED BY B + D NEUTRONS.

Tracks measured make angles up to ± 12° with plane of the plate. Range is plotted in microscope eyepiece scale divisions.

The bands shown in Fig. 2 are drawn by assuming a 'width' of 0·8 eMv. in the range at any angle due to straggling, and an uncertainty of ±3° in the determination of β due to factors (*b*) and (*c*). The results for the first 500 tracks measured are shown as points in Fig. 2, and it will be seen that 90 per cent of the tracks lie within the four bands. The results emphasize in a striking way one of the conclusions of the previous letter, that the photographic method has the advantage over the expansion chamber in that the amount of matter in the plate is so small that it does not give rise to scattered neutrons in serious numbers, and show that it is possible to investigate neutron-proton scattering at high energies by the photographic method. The measurements are proceeding.

The possibility of determining γ-ray energies by means of the photographic plate has also been investigated. Plates loaded with heavy hydrogen were exposed to the γ-rays from fluorine under proton bombardment and a search made for the photo-disintegration protons. The difficulty is that the cross-section per atom for the production of electrons in the emulsion by the γ-rays is about a thousand times greater than that for the photo-disintegration of the deuteron. Although many electrons must pass through a grain before it will develop, a limit is thus imposed on the time of exposure to which the plate can be subjected, beyond which the general background of fog makes it impossible to distinguish proton tracks. With the first plates available the deuterium content was too small to give a sufficient number of tracks per sq. cm. of the plate at the limiting γ-ray exposure. A layer of 'heavy' ammonium chloride, $(ND_4)Cl$, was therefore supported immediately above an ordinary half-tone plate during an exposure to the γ-rays. A large number of proton tracks was then observed in the developed plate, starting in the surface of the emulsion, and having a maximum energy of 2 eMv. We attribute these to the photo-disintegration of the deuterium under the action of the 6 eMv. γ-rays from the fluorine.

Although the application of the method to the determination of γ-ray energies can only be made in the absence of neutrons, it can be used in its present form to determine the spatial distribution of protons from the photo-disintegration process, an experiment which is of great importance for the meson field theory. This experiment, and further work with plates loaded with greater amounts of heavy hydrogen, is proceeding.

It is evident from the results published in our previous communication on the protons from the reaction $B^{10}-d,p$ that the photographic method can be applied to scattering experiments between fundamental particles, p—p, p—d, p—α, etc., using the high-energy protons provided by the cyclotron, and we are at present collaborating with Prof. J. Chadwick on such experiments. Dr. T. R. Wilkins kindly informs me in a private communication that he is investigating proton-proton scattering at high energies by a similar method. The great advantage of the method for such work is that, in contrast with experimental methods employing counters, the particles scattered through different angles are all recorded at the same time, so that it is not necessary to apply elaborate corrections for maintaining the constancy of the bombarding stream or correcting for its variation. The analysis of the plates is much easier in these experiments than with neutron work, since the scattered particles all start in the surface and run parallel into the plate. Dr. Wilkins employs a camera carrying a large number of plates in this

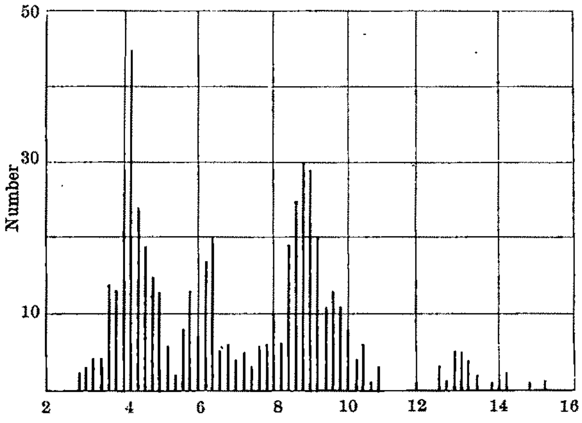

Fig. 3.

ENERGY DISTRIBUTION FROM ALL MEASURED TRACKS PROJECTED WITHIN 40° OF THE DIRECTION OF THE INCIDENT NEUTRONS.

type of experiment. We use a single rectangular plate with the proton beam running parallel to the long axis and a little above the plate. The beam, defined by stops, passes down the axis of a tube provided with a short interruption through which protons scattered by the gas in the camera can emerge to enter the plate.

A detailed account of the methods employed will shortly be submitted for publication in another place. It may be mentioned here that we find it a considerable advantage to use binocular microscopes and optical equipment of the highest quality to reduce the nervous strain on the observer to a minimum. Although the Ilford half-tone plate has proved very adequate for the work, it seems likely that it will be possible to develop special plates with superior characteristics for nuclear work.

THE VOCODER

AT the World's Fairs in New York and San Francisco great interest was shown in the speech synthesizer shown in the Bell System exhibits. In the December number of the *Bell Laboratories Record*, H. Dudley, of their research department, describes this device, known as the 'vocoder'. The 'voder' is an offshoot of a more extensive system first demonstrated in its experimental stage several years ago. It first analysed spoken sounds and then used the information to control the synthesizing circuit. As World's Fair displays were then under consideration it was seen that the synthesizer, manually controlled, could be made into a dramatic demonstration. Development was at first concentrated in this field, but when a successful Voder became assured, attention was shifted back to the broader and parent system and it was called the 'vocoder', since it operates on the principle of deriving voice codes to re-create the speech which it analyses. The analyser is at the left and the synthesizer at the right of the vocoder.

Electrical speech waves from a microphone are analysed for pitch by one channel and for spectrum by a group of channels. In the pitch analysis the fundamental frequency is called for simplicity the pitch. It is measured by a circuit containing a frequency discriminating network which obtains the frequency in a pure form, a frequency meter for counting, by more or less uniform pulses, the current reversals therein, and a filter for eliminating the actual speech frequencies but retaining a slowly changing current that is a direct measure of the pitch. The output current of the pitch channel is then a pitch-defining channel with its current approximately proportional to the pitch of the voiced sound and equal to zero for the unvoiced sounds.

There are ten spectrum-analysing channels, the first handling the frequency range 0–250 cycles and the other nine, the bands, 300 cycles wide, extending from 250 cycles to 2,950 cycles, a top frequency which is representative of commercial telephone circuits. The operation of the analyser is illustrated by a group of oscillograms taken in analysing the sentence "She saw Mary". In the analyser the speech wave is the input and the eleven speech-defining signals are the output; in the synthesizer the eleven speech-defining signals are the imput and the speech wave the output. The relaxation oscillator is the source of the buzz, and the random noise circuit the source of the hiss. When a voiced sound is analysed a pitch current other than zero is received, with the result that the buzz is set for the current pitch by the "pitch control" on the relaxation oscillator; also, the relay marked "energy source switch" operates, switching from the hiss source to the buzz source. From the loud-speaker comes speech approximately the same in pitch and in spectrum as the original.

The possibilities of the Vocoder were recently demonstrated by the author before the Acoustical Society of America and before the New York Electrical Society. In these demonstrations comparison is first made between direct speech and the best re-creation that the apparatus could make. Then by manipulation of dials and switches, speech is modified in various ways. Normal speech becomes a throaty whisper when the hiss is substituted for the buzz. Although the hiss is relatively faint, it is shown to be essential for discrimination between words like 'church' and 'shirts'.

Ordinarily the re-created pitch moves up and down with that of the original. If variation is prevented, the re-created speech is a monotone like a chant. When the relative variation is cut in half, the voice seems flat and dragging; when the swings are twice normal, the voice seems more brilliant; when four times normal it sounds febrile and unnatural. The controls can be reversed, so that high becomes low; the tune of a song is then unrecognizable, and speech has some of the lilting characteristics of Scandinavian tongues. By appropriate setting of the basic pitch, the voice may be anything from a low bass to a high soprano. If the basic pitch is set to maintain a constant ratio of, say, 5 to 4 to the original, this is a 'major third' higher and harmonizes with the original. In two-part harmony, the demonstrator can then sing a duet with himself. Connecting a spare synthesizer for a 3 to 4 ratio he can sing one part in a trio, the others being taken by his electrical doubles. Finally, with the basic pitch control of the apparatus, he becomes a father reprimanding his daughter, then the girl herself, and then becomes the grandfather interceding for the child. Keeping careful time with the puffs of a locomotive, the demonstrator can make the locomotive puff intelligibly "We're—starting—slowly—faster, faster, faster" as the puffs come closer together. A particularly striking effect is that of singing with an organ to supply the tones. Although the words may be spoken, the demonstrator usually sings them to hold the rhythm. It makes no difference whether his voice is melodious or not; the tonal quality comes only from the musical source.

The engineering possibilities which may grow out of the application of the principles employed in this device are hard to predict at the present time. The speech-defining currents, however, do have features of simplicity and inaudibility which may open the way to new types of privacy systems or to a reduction in the range required for the transmission of intelligible telephonic speech.

CATLIN AND HIS NORTH AMERICAN INDIAN GALLERY AND MUSEUM

BY L. J. P. GASKIN

FEBRUARY 1 is the centenary of the opening of "Catlin's North American Indian Gallery and Museum" in the Egyptian Hall, London. George Catlin, American artist, traveller, and ethnographer, spent eight years, 1830–38, among the Plains Indians of North America, and was familiar with their life and customs at a time when the Indians were still living far from that civilization which was to overtake and destroy them so rapidly. His declared purpose from the outset was to preserve for posterity the likeness of aboriginal man in America, and his artistic ability and industry in this direction was shown to great advantage by more than six hundred portraits and sketches of the Indians, and of Indian life, hung round the walls of the Egyptian Hall. The Museum contained thousands of objects of Indian manufacture such as weapons, costumes, musical instruments, and domestic utensils so arranged as to form a pictorial history of those tribes thought particularly worthy of notice. In the centre of the room was erected a large wigwam from the country of the Crow Indians, made of buffalo skins, curiously ornamented with porcupine quills, and capable of housing eighty persons.

The history of the exhibition is interesting. After a four-year sojourn in London and the provinces it was removed to Paris, where it attracted the attention of Louis Philippe, who permitted it to be shown in the Louvre. Unfortunately, this Royal interest involved Catlin in great difficulties when the July Revolution of 1848 compelled him to leave France. Once again in London, he sought to recoup his losses by the rehabilitation of his exhibition, and this led to financial disaster: his collections were seized for debt, though they were freed later through the generosity of a fellow-countryman.

In 1852, Catlin set out on his travels once again, and on this occasion visited Central and South America. He returned to Europe in 1858, and busied himself with the formation of his "Cartoon Collection", copies of his original pictures, and much new matter from his later travels. He returned to America in 1870 to show this second collection in the Smithsonian Institution, and died in 1872.

For forty-two years he had laboured to improve and perfect his Indian collections, and to plead the Red Man's cause. His writings, particularly his "Letters and Notes on the manners, customs, and condition of the North American Indians" (1841), made him and his work known to a large circle of readers in Europe and America, and his portraits and sketches have been declared, by those well qualified to judge, as among the most truthful of the Red Indians ever presented to the public. But the most enduring monument to his memory will always be his two collections, now housed in the United States National Museum and the American Museum of Natural History.

NEWTON'S KNOWLEDGE OF THE RADIUS OF THE EARTH

IN a paper entitled "The Story of Newton's Inverse Square Law and his Use of a False Radius of the Earth" (*J. Brit. Astro. Assoc.*, 50, 2; 1939), John Miller states that the story of Newton's alleged ignorance of the true radius of the earth is open to considerable doubt. The data at the disposal of Newton were the time the moon required to revolve around the earth and the moon's distance from the earth in terms of the earth's radius. The latter was known from the days of Greek astronomy to be about 60, and this was independent of the true radius of the earth. A few simple formulæ are derived by Mr. Miller, and from these a relationship is established between the true radius of the earth and certain constants, the basic assumption being the inverse square law. Miller's final formula enables the true radius of the earth to be found, but, of course, if a false value of the radius is used in this formula, the equality breaks down; in other words, the inverse square law seems invalid. It is alleged that Newton took the radius of the earth to be 3,440 miles, and as it was impossible to fit this value in with the inverse square law, his work was delayed nearly twenty years.

It is generally believed that Newton accepted the value of one degree of latitude as 60 miles, hence his difficulty with the fictitious radius of the earth, but, as Miller points out, Snell's measurement in 1617 gave 66·6 miles and Norwood showed in 1637 that 69·5 miles was a close value, while two years later Picard found a more accurate result, slightly less than Norwood's. It is remarkable that Newton did not make use of any of these in 1665–66 when he was engaged on his gravitational theory at Woolsthorpe. It is certain that he knew Snell's value in 1672, ten years before he was supposed to have recomputed his earlier results, because Varen's "Geography", published in 1672, contains an error which Newton corrected by using Snell's value for the length of a degree of latitude. Picard's accurate results were communicated to the Royal Society in 1672 on the day that Newton was elected a fellow, yet the story goes that he did not make any use of these until 1682. This delay of ten years seems inexplicable.

From an examination of the evidence from various other points of view, Mr. Miller concludes that the story is unauthenticated and that the real reason for Newton's delay of seventeen years in the publication of his "Principia" was the difficulty that he experienced in dealing with axial rotation, a problem to which Miller hopes to return in a subsequent paper.

ELECTRICITY AND GAS INSPECTION SERVICES IN OTTAWA

THE annual report of the Electricity and Gas Inspection Services of Ottawa for the fiscal year, ended March 31, 1939, has been published (Ottawa: King's Printer. 25 cents). It is addressed to the Department of Trade and Commerce, and describes the activities of the Electricity and Gas Inspection Branch from March 1938 until February 1939, with the work performed during the previous year. So far as the Electricity and Gas Inspection Services are concerned, the work performed creates a record. The total revenue was £2,400 more than the preceding year and there were 21,000 more meters tested. A decrease in the surplus is mainly due to the fact that the salaries of the headquarters staff are included in the statement for the first time. The amounts required to cover rent, fuel and furniture for the Services as a whole are not included in this summary. The expenditures incurred in the administration of the Electricity and Fluid Exportation Act are included in the amount charged against electricity inspection. This amounted to about £40.

Calorific tests of manufactured gas were made throughout the Dominion and the average heating value was found to be 489 B.T.U. per cubic foot. The standard required is 450 B.T.U. per cubic foot. The amount of natural gas supplied throughout Canada during this period was approximately 32,000 million cubic feet, an increase of 5½ millions over last year. The total number of meters in service on March 31, 1939, was approximately two million, an increase of nearly 60,000 over the preceding year.

The periodic calibration and checking of the inspection standards, supplied to the various inspectors throughout Canada for outside companies and other departments of the Government, is performed in the laboratories of Ottawa, Winnipeg and Vancouver. The expenditure on electricity inspection was £55,000 and on gas inspection was £15,000.

The number of kilowatt-hours of electrical energy produced for export during the fiscal year 1938–39 was 1,940 million, an increase of 100 million over the preceding year. The number of kilowatt-hours produced for use in Canada by the exporting companies was 3,100 million electric units, as compared with 4,132 million during the previous year. The revenue collected by virtue of the export duty of 0·03 cent per electric unit shows a slight increase over the preceding year.

The Range Oil and Gas Company exported approximately 289 million cubic feet of natural gas from the Rogers Imperial structure in southern Alberta during the past year; and the Vanalta Oils, Ltd., exported approximately 27 million cubic feet from the Red Coulee field, also in southern Alberta. No revenue, except the licence fee, ten pounds for each licence, is obtained from this export.

THE McCOMB-ROMBERG SEISMOMETER

MODELS of this new tilt-compensation seismometer have recently been placed in the new seismographic station of the Nebraska Wesleyan University in Lincoln, Nebraska, in the Chicago Seismograph Station, and in Salt Lake City ("New Instruments and Equipment at Coöperative Seismograph Stations of the United States Coast and Geodetic Survey", J. H. Nelson and H. E. McComb, *Bull. Seis. Soc. Amer.*, 29, No. 4, 549–588; Oct. 1939).

A few of its salient features are as follow: It rests on a one-piece brass plate having point-slot-plane positions for the seismometer footscrews. Around the edge of this base plate is a ploughed slot in which the edges of the metal cover rest Air currents and dust are effectively kept away from the boom and optical system. The column is relatively short and well braced against possible side sway. At the top of the column a worm-driven windlass provides easy and accurate adjustment of the length of the supporting wires from which the steady mass is suspended. The boom, a duralumin rod about 12 in. long has at one end a sapphire jewel which rests against a steel pivot mounted in the bottom of the column, and at the other end a vane of electrolytic copper which floats in the field of a cobalt steel permanent magnet. A rough auxiliary pivot with slow-motion screw mounted on the column to work against a brass cup on the boom is provided for protecting the main pivot and jewel at times of installation and adjustment. The mass is of brass, weighing 2,550 gm. The boom, damping vane and oil cup weigh about 130 gm. The magnet is mounted on guides and may be readily removed at times of determining free period and recording decay curves. The air gap may be easily adjusted by means of a knurled-head micrometer screw.

The optical system of multiplying lever and mirrors gives a nominal magnification of about 350. The seismometer cover is of thin sheet aluminium, provided with doors for adjustments and a glass window set so as to reflect stray light downwards and not into the optical system. Both the north-south and east-west components record on one Henson recorder. The speed of the drum is 15 mm. per minute (one revolution per hour), translating about 5 mm. per revolution. It is driven by a 60-cycle 110-volt synchronous motor through a train of cut gears. A single seismogram 12 in. × 36 in. in size is obtained. The east-west component records directly whereas the north-south component operates by reflection from a large first-surface mirror which gives no distortion.

Tyndall on Haze and Dust

THE Friday Evening Discourse entitled "On Haze and Dust" delivered by Prof. Tyndall at the Royal Institution on January 21, 1870, is printed in full. Prof. Tyndall referred to experiments carried out at the Royal Institution, in which he passed a "powerfully condensed beam" of light through tubes originally exhausted and "optically empty", to which air from the laboratory was admitted after passing through potash and sulphuric acid. In every case, floating matter entered the tube, and revealed itself by scattering the light, showing the "conical track of the electric beam". If the air was heated before passing through the drying apparatus, the floating matter was burnt up. "It was therefore *organic matter*". Tyndall then tried different methods of heating the air stream. Imperfect combustion of the particles produced fine blue clouds in the experimental tube, which gave perfectly polarized light at right angles to the illuminating beam. He also reported experiments in which a heated body placed below a cylindrical beam of light produced wreaths of blackness like thick black smoke, due to air currents removing the scattering particles which made the beam visible.

Tyndall then went on to associate the "organic matter" which the flame consumes with the germs causing disease. For this he was taken to task in the leading article in the same issue. "Practically, so far as health is concerned, Prof. Tyndall has given us a scientific account, not only of certain optical properties of impure air, but likewise of the benefit of several popular practices, such, for example, as lighting fires during epidemics to purify the air, the use of gauze curtains in malarious districts as a protection against fever, covering the mouth with a cloth during sleep in fever countries, and the like . . . On the real proximate aerial cause of disease, if such there be, no new light has been yet thrown either by the optician, the microscopist, or the chemist."

FROM a correspondent: "Professor Struthers, of Aberdeen, and Professor Bell, of St. Andrews, hearing that the five ladies who are studying at the Edinburgh University are excluded from the opportunity of studying anatomy there, have severally offered their services as instructors. Many a lady will rejoice that the numbers of those willing and ready to help in the good cause of fuller knowledge for women are increased by two professors, who have bravely come forward with much moral courage and chivalrous feeling."

"WE are happy to be able to announce that the council of the Chemical Society has decided to have a report of their proceedings and an abstract of the papers read before the society drawn up immediately after its meetings, and to offer copies of this report to the editors of journals who may be likely to wish to publish it. The days when the newest results of science were regarded as something secret—or, at all events, of no concern to the ordinary man of education—are gone by, we trust, for ever."

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR IN BACTERIOLOGY—The Registrar, University, Leeds (February 3).

AN APPOINTMENT IN THE MECHANICAL ENGINEERING AND TRANSPORTATION (POWER) DEPARTMENT of the Indian State Railways—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (quoting Appointment 1/4A) (February 12).

LECTURER IN AGRICULTURAL BIOCHEMISTRY in the Massey Agricultural College, Palmerston North, New Zealand—Universities Bureau, 88a Gower Street, W.C.1 (April 15).

TECHNOLOGISTS—The Under-Secretary of State, S.2.G., Department Z.A., Air Ministry, Adastral House, Kingsway, W.C.2 (quoting reference number B.380).

TEMPORARY FORECASTERS, Grade II (Male) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

SCIENTIFIC PLANNING OF LOCAL GOVERNMENT

IT is becoming a commonplace to say that war is no longer an affair of armed forces alone. Curtailed lighting, restrictions on travel whether by road or by rail, national registration, the rationing of food and of petrol, the exigencies of civil defence, and many other measures have brought home to all that national needs and effort must, on occasion, override all personal and individual considerations. Nothing can be allowed to stand in the way of our immediate purpose, which is to win the war, with the view of establishing an order based on the peaceful settlement of international disputes.

It would be disastrous, however, if the restraints necessarily imposed on individuals in a time of war engendered merely a sense of frustration. Behind even the prosecution of the war lies the purpose of safeguarding our national life and existence, for it is the preservation of our mode of life, with its traditions and heritage of justice and freedom, that has called forth this effort. Nevertheless, the very disturbances and shocks administered to the structure of our national life may loosen obstacles that have hindered its development in the past. Amid all the tragedy and wreckage of war, any opportunity which it may afford to redeem the mistakes of the past should not be forgotten.

There are few fields of planning in which to some extent fresh opportunities are not opening up and possibilities of further progress and development appearing. The organization of national defence has given a fresh impulse to many forces making for regionalism, the co-ordination of local authorities or of public services, the control of the location of industry and like matters. Under the exigencies of war, fresh experience is being gained which should ultimately be of value in the reintegration and development of national life, both under local authority and central government. Particularly is it true that the organization of civil defence, whether in the actual precautionary services against air attack or in the dispersal of population in evacuation schemes, has exposed defects in our administrative system which should be rectified at the first opportunity.

Notable among such weaknesses are the difficulties which local administrative units, often with archaic and thoroughly unscientific boundaries, can put in the way of a uniform and adequate plan of defence; and the failure of such bodies to appreciate the differences between urban and rural conditions and to apply measures appropriate and adequate in each sphere. It is not easy to assess the wastage which has been caused by such weaknesses; but an attempt should be made not merely to eliminate such waste but also to deal with its underlying causes.

An outstanding contribution in this field is Dr. W. A. Robson's study "The Government and Misgovernment of London", which appeared a short time before the War broke out. The attention of scientific workers has already been directed to this book in these columns (NATURE, 144, 846; 1939), but much of the third part of Dr. Robson's book is of general validity and far from being confined to the particular question of London. The issues of regionalism, the principles of democracy involved, no less than those of planning, affect more or less acutely, problems of national and local administration throughout Great Britain, and the stimulating discussion of these matters deserves the careful attention of all those who are determined to seize any fresh opportunities which the testing time of war may present.

Regional reorganization, whether in London or elsewhere, is not necessarily a political question in the party system at all. There is little reason to believe that any political party would gain or lose much by the introduction of reform and, in the main, all are in favour of administrative efficiency as they understand it.

If, however, on political grounds reconstruction is not likely to meet real difficulties, strong opposition may be encountered from the numerous local authorities whose prestige or even existence might be affected. Dr. Robson directs attention to the importance of this appearance of vested interests in local government and to the need for investigation by competent sociologists. There is an obvious need for impartial scientific investigation. The picture of muddle and frustration which Dr. Robson draws is far from being a matter of local concern. The organization of London's government is a national question calling for national leadership and direction. Solution of the problem on such scientific lines as suggested by Dr. Robson would, moreover, have effects reaching far outside the boundaries of even Greater London. Not merely would a great impetus be given to regionalism, but also experience would be forthcoming which would contribute immensely to the wise planning of national resources and the effective handling of the intricate issues involved in the national planning of transport, the utilization of land and the preservation of amenities.

What is clear is that the whole question still offers a wide field for investigation or research. Municipal research is in fact largely unknown in Great Britain, and most municipalities are content to carry out their own investigations independently of the experience or practice of others. There is no information service available for municipalities to promote co-operation in the study of problems of municipal administration, and there are few signs of any desire for such co-operation. The recommendation in the report on the location of industry issued by Political and Economic Planning (P E P) for the establishment of a central information service on industrial siting (see NATURE, 143, 770 ; 1939) is essentially a step in this direction, but much more definite study and investigation are required. Regional problems require separate study, and above all study inspired by the belief that regions are not congeries of local units. The need for comprehensive improvement must be admitted, and the investigations prompted by a broader view and higher statesmanship. Only in such a spirit can we hope for effective experimentation with plans for federal or dual metropolitan government, and acquire the basic experience or use it wisely.

When all allowance has been made, however, for the need for fuller investigation on particular issues, it cannot be denied that there is already available an immense amount of knowledge which, if pooled and really utilized, would permit a much more effective co-ordination of national and local resources. The urgent necessity for economy in both local and national administration is a further reason for action. Unless some real attempt is made in London and elsewhere to find a regional solution on scientific lines for these interlocked problems of the chains of towns for which Patrick Geddes introduced the term 'conurbation', so far from the resources of the nation being husbanded and expended to the best advantage, we are likely to see yet further waste and frustration, through short-sighted economy starving essential services and neglecting bold and far-reaching measures which would eliminate the meaningless rivalries, overlapping and duplication so often encountered at present.

To secure action it is not enough to have an adequate plan and programme. Equally essential is a public opinion among the electorate alive to the possibilities and determined on reform. Unfortunately, as Prof. H. A. Mess pointed out a year ago in an able article in the *Political Quarterly* (9, 389 ; 1938), there are factors tending to weaken civic consciousness, and new cohesive devices and new forms of government may be required to develop civic consciousness in, for example, Greater London. At the best, in a new town there is a considerable time-lag before consciousness and sentiment adapt themselves to the new situation, and still longer before there is a change in local government.

This matter of local sentiment and public opinion is not entirely a matter of education. The term 'local sentiment' is ill-defined and often absurd. It would be hard to answer such questions as in whose minds it is found, how widely it is diffused, how strong it is and in what kind of attitudes and actions it results. The analysis by sociologists of such questions as these and others involved in the rise and decay of towns should be as valuable to those faced with the practical problems of administration as to those concerned with the education of the electorate in citizenship.

From whichever side we approach such problems, whether from that of education, the investigations which lead up to the planning, or the technical aspects and administrative detail of the planning itself, the responsibilities and opportunities of scientific workers are unmistakable. If we are to build, with resources impaired if not crippled by the sacrifices and vicissitudes of wartime, a social order in which the advantages which modern science has put at our disposal are more freely and fully utilized, and the present obstacles to that utilization or the forces dissipating our resources have been eliminated, scientific workers must play a major part. No defeatist spirit can be tolerated. Only as men and women, whether scientific workers or not, address themselves hopefully and adventurously to this creative task, ready to seize whatever opportunities may come and resolved that no inherited prejudices or vested interests of administration or property shall be allowed to injure the common welfare, can we hope to build cities and communities which will enjoy the true abundance which might be ours. We must be planning for that future even in the stress of war, if we are to be ready when the opportunity comes to transmute our dreams and visions into the cities, workshops and homes of a new era of civilization.

FUTURE OF ZOOLOGY IN INDIA

A LONG series of volumes, bearing the title of "The Fauna of British India", has been published under the authority of the Secretary of State for India, with the object of ensuring that the rich fauna of that great continental area is made properly known and, at the same time, of providing authoritative means for its identification. While its inception is more than fifty years old, the wisdom in launching this project has become increasingly justified in recent years. The first volume, which dealt with part of the Mammalia, appeared in 1888. The latest volume, also dealing with Mammalia, was issued in 1939 and is reviewed on the next page. Throughout this period, one or more volumes have been issued almost every year. During the War of 1914–1918, five volumes were published.

The "Fauna of India" has become increasingly used in Indian universities, colleges and museums. Furthermore, certain of the volumes rank as essential tools in the work of the scientific staffs of those Government departments concerned with agriculture, fisheries, forestry and tropical medicine; and indeed, certain forthcoming volumes promise to be of special importance in this respect. The "Fauna" series aims at providing accurate descriptions of all species of Indian animals and, thereby, forms the basis upon which further study depends. The importance of accurate identification scarcely needs stressing, whether it be, for example, of a mosquito concerned with disease transmission, an insect devouring a crop or an animal of solely scientific interest.

This primary object of the "Fauna" is being gradually achieved, but there is still a long and uphill road to traverse. For one thing, some of the earlier volumes are now out of date and need revision in the light of increased knowledge. Many divisions of the animal kingdom have not yet been dealt with, and there is the added difficulty of finding competent specialists willing to undertake the monographing of certain important groups. The Termites are a case in point, as they rank among the most destructive of Indian insects; little progress is being made in their study, mainly owing to difficulties attending their identification.

We learn with regret that the Secretary of State for India has decided to cease publication of the "Fauna of British India" for the duration of the War. While recognizing the present necessity for economy, it needs emphasizing that much of zoological progress in India may become involved in this decision. It behoves those who have such progress at heart to combine their efforts and do all that is possible to discourage any policy directed towards further economy, possibly resulting in the cessation of the publication of the "Fauna of India" altogether. Such an outcome would, in the long run, heavily counterbalance any monetary savings achieved.

The projected dominion status for India is linked with the growing part being played by Indians in the scientific development of their country. In this latter connexion they need every help that we can provide. From the zoological point of view, the least we can do is to ensure the continuance of this long-established publication.

THE MAMMALS OF INDIA

The Fauna of British India, including Ceylon and Burma

Edited by Lt.-Col. R. B. S. Sewell. (Published under the Patronage of the Secretary of State for India.) Mammalia. Vol. I: Primates and Carnivora (in part), Families, Felidae and Viverridae. By R. I. Pocock. Pp. xxxiii+464+31 plates. (London: Taylor and Francis, Ltd., 1939.) 30*s*.

BLANDFORD'S "Mammals of British India", published in 1888 and 1891, has until now been the standard work on the subject, and useful as that has been, it had for some years been regarded by zoologists as out of date, since a vast amount of additional knowledge on the subject has been gained in the last half century. A new edition that would embody the latest views on classification and the experience of sportsmen and travellers was greatly needed, and in 1923 Mr. Pocock, an eminent authority on the mammals of the world, undertook the task, little realizing the length of time that would be required owing to the vast amount of material to be handled and examined and the extent to which names of species and races required revision.

Formerly species were recognized mostly by their external appearance and local races regarded merely as varieties, whereas now careful measurements of the skulls and, where possible, other parts as well, has to be carried out. Well-defined local races are distinguished by the trinomial method of nomenclature.

That the work has been done with the utmost pains and thoroughness is clear from a perusal of the present volume, which deals with the orders Primates and Carnivora (in part). Of the former, British India possesses two species of gibbon, *Hylobates hoolock* and *H. lar*, these being the only representatives of the man-like apes, though the more ordinary types of monkeys are well represented by the macaques and langurs or leaf monkeys and the lemurs by the lorises.

Of the monkeys proper the author recognizes three distinct races of the rhesus in British India, the typical race occurring throughout nearly the whole of northern India and to a great extent Burma as well. This, the best known of all the monkeys as it is largely imported alive into European countries, although not regarded by the Hindus as sacred, is nevertheless left unmolested and so has become a very familiar object in native villages.

The lion-tailed macaque, also known as the wanderoo monkey, is certainly the most striking in appearance on account of the large growth of grey hair surrounding the face and the glossy black hair of the remainder of the body, but it is rare and keeps strictly to the thick forests of the Western Ghats.

Of the small lemurs, or lemuroids, the slow and slender lorises are well known, but research has shown that of the former there are no fewer than four and of the latter six distinct races. All are strictly nocturnal, sleeping bunched up in the fork of a tree by day, when they have much the appearance of the little spotted owl (*Athene brama*) and "the same habit of swaying the head and, when fighting, utter a similar screech". At the approach of darkness they creep forth and capture their prey "after a stealthy approach, with a lightning grab of both hands, and hold it in a tenacious grip while devouring it."

The greater part of this volume deals with the Carnivora, in which the author admits that classification is difficult. Of the Felidæ the zoologists of old grouped all in the genus *Felis*, with the one exception of the cheetah or hunting leopard which was distinguished by its so-called non-retractile claws; but Mr. Pocock finds that this animal is actually more nearly allied to the ordinary cats than the latter are to the lions, tigers and their near relations. He places the great cats (lions, tigers, etc.) in a separate subfamily, Pantherinæ, the more ordinary cats in that of Felinæ, including a number of genera, while the hunting leopard alone occupies the subfamily Acinonychinæ.

The lion was formerly abundant in northern India; but is now nearly extinct there, the few that remain being restricted to the Gir Forest in Kathiawar, where they are protected. The author believes that it made its way into India through Persia and Baluchistan in comparatively recent times and was not there long enough to penetrate far southwards. Its near extermination has been brought about by human persecution and not, as has often been suggested, by competition with the tiger.

This volume will surely rank as a very worthy member of a fine series.

D. SETH-SMITH.

GREY OWL: NATURALIST

Half-Breed
The Story of Grey Owl (Wa-Sha-Quon-Asin). By Lovat Dickson. Pp. xii + 346 + 12 plates. (London: Peter Davies, Ltd., 1939.) 10*s*. 6*d*. net.

"Grey Owl went to his last resting place as he would have wished. . . . As the sun set on Lake Ajawaan, the burial party turned back to town, one hundred miles distant, leaving Grey Owl among the birches and pines he so much loved, at peace in a remote and lovely grave."

THAT was in 1938, and thus was marked the end, at the early age of fifty years, of one of the most intriguing personalities that graced modern times. But it also marked the beginning of a rumpus which raged for some considerable time after his death. Grey Owl or Wa-Sha-Quon-Asin, a self-styled North American Indian, was shown to have lived his younger days in Hastings and attended the Grammar School there. His name was Archie Belaney, and his aunts still live in that town. Had he hoaxed the world, or was there a conundrum demanding thorough investigation? Mr. Lovat Dickson, Grey Owl's friend and confidant, spared no pains in his endeavour to establish the truth. But it seems that the whole truth may never be told. That he was not a full-blooded Indian of the Ojibway tribe is now certain; but that he was a pure 'white' is uncertain. It depends upon the origin of his mother, which so far has not been thoroughly traced. But after carefully examining the details meticulously recorded by his biographer, it seems impossible not to believe that he was a half-breed. For if he was not, then much of his behaviour, and indeed his very physical appearance, are incomprehensible.

Interest in that aspect of Grey Owl has naturally died down somewhat, but Mr. Lovat Dickson's book will arouse afresh and with even greater vigour interest in Grey Owl as a human personality and especially as a naturalist. During the present time of increasing interest in the teaching of biology and natural history, the book will prove of inestimable value for the inspiration that Grey Owl has given; for he was no mere sentimentalist where animal life was concerned. True, he loved animals, and in loving them learned *how* to study them, for, as one great zoologist once quoted in parody:

"He studieth best who loveth best,
All things both great and small."

"Here [at Ajawaan] he will live out his days, knowing only these animals and birds that he loves and who love him, sharing in their joys and sorrows, their triumphs and disappointments: watching them mate and sharing their parental triumphs; guarding them as best he can from Death, the only intruder who can do them harm." This is surely field natural history at its best: doubtless an unattainable ideal for most of us who have to live and study in less rural or less congenial surroundings, but at the same time an inspiration to achieve the best methods possible. In schools and colleges, much can be done by keeping and studying animals in captivity. Grey Owl's methods can be adapted to such less ideal conditions, so that the aquatic animals in the aquarium, the frogs in the frog pond, and the rabbits in their run receive the consideration which is their due. Love of Nature will naturally follow (if it is not already there), and just as Grey Owl, through the influence of his wife Anahereo, became converted from a killer to a conservator of wild life, so will students of natural history and biology become imbued with the desire not only to learn but also to preserve. It will not be necessary then to teach students, for example, that when gathering material for study only the minimum should be taken, and when they intend to study twigs in winter or summer they should never take even one twig from a sapling, thus disfiguring the tree for life. A host of ideas for field work, too, can be culled from this study of Grey Owl's life.

Even as a boy, Archie Belaney valued animals as living creatures, not as dead trophies. At Hastings he was allowed to keep his "friends", including snakes, frogs, birds, silk-worms, and rabbits, in a room at the top of the house. One is struck by the similarity between this boy and the boy Raymond Ditmars who kept his menagerie at the top of a house in New York. The former finally became a conservator of wild life under the Government of Canada; the latter is a curator in the New York Zoological Park and is still one of America's leading naturalists.

Through his very obvious desire to give a faithful biography of this truly wonderful man, Mr. Lovat Dickson may not even realize himself how much Grey Owl's love of Nature as here recorded will prove a unique source of inspiration to many students of plant and animal life; and the tenacity and singleness of purpose of Grey Owl is an absorbing study in itself. In his younger days he showed not so much a stubborn impatience with stiff English life as a strict determination to achieve a purpose. He achieved more than his purpose. He learned that it was undignified as well as unwise to take more of the fruits of the earth than one needed. He also achieved a keen sense of values, for he himself wrote: "You still believe that man, as such, is pre-eminent, governs the Powers of Nature. So he does, to a large extent, in civilization, but not on the Frontier, until that Frontier has been removed." Later, of his adopted tribe, he said:

"Nature is to us a sanctuary. To the Indian all Nature is sacred. All things are in accord, all part of the one great plan, Creation. . . . Thus, the Indian attitude towards Nature. Thus his philosophy—that not only man but all living creatures of the forest have a right to live, to freedom, a right to be happy in their own way, a right to a place in the sun."

The book never lacks interest. For reasons already given it should be read by teachers of biology, natural history and psychology; all students of these subjects should read it, too, and we strongly recommend that it be given a place on the shelves of school libraries for the benefit of older pupils. Mr. Lovat Dickson's absorbing style transports the reader to the open tracks and great forests of Canada where the sough of the birches and pines can almost be heard, while it seems impossible never to have met Jelly Roll, McGinnis and McGinty and the other animal characters which antic and prattle their parts through the narrative.

This raises a point to which the reviewer would direct the attention of Mr. Lovat Dickson. The book as it stands will be read by, and surely satisfy, many who knew of, and appreciated, the work of Grey Owl; it should also command the attention of biologists and natural historians; but it is not suitable—indeed is not meant—for younger children. For example, Grey Owl's apparent views on marriage would not be compatible with those of the average 'civilized' white man. But Grey Owl obviously loved children as he did other animals. He came into contact with many thousands of young admirers throughout the world. He wrote for them, he lectured to them (only the fact that he refused not to mention the "controversial" subject of fox-hunting prevented him from broadcasting to them during one of his rare visits to Great Britain). A "Life of Grey Owl" suitable for younger children would be a source of inspiration to them—an example of nobility of character (too often left to more warlike heroes to set) and, more important, a leader in the most desirable way of studying life around them.

LANDMARKS IN NEUROLOGY

Selected Writings of Sir Charles Sherrington
A Testimonial presented by the Neurologists forming the Guarantors of the Journal *Brain*. Compiled and edited by D. Denny Brown. Pp. xiv + 532. (London: Hamish Hamilton Medical Books, 1939.) 25*s*. net.

NEUROLOGISTS will open this volume with the highest expectations and will not be disappointed. It is a testimonial to Sir Charles Sherrington made up of extracts from his writings and edited by a colleague who has been in close touch with all his later work. True, it would need an incredibly bad editor to spoil the effect of such remarkable material, but Dr. Denny Brown has been a very good editor indeed. By a careful choice of extracts and the use of occasional connecting passages he has made a series of chapters, each complete in itself and each dealing with a particular theme. Some of the chapters are mainly derived from early papers, for example, on the nerve roots, some from the work at Liverpool or at Oxford, but most of them contain extracts from several sources and show the development of the subject in Sherrington's hands as well as his final judgment on it. We see the detailed mapping of motor and sensory supply, followed by the classical analysis of reflex activity in the spinal animal. Several aspects of reflex co-ordination have chapters to themselves, and considerable space is naturally given to the discussion of reciprocal innervation. One chapter is derived from the paper with Grünbaum on the motor area of the brain, and the last two deal with more recent work on the intimate nature of excitation and inhibition and on the adjustment of muscular contraction. There has been no attempt to include many of the topics dealt with in the book which had such a decisive effect on the progress of neurology, the "Integrative Action of the Nervous System", for the present volume is designed as a companion and a supplement to it.

The editor has done his work so well that the reader very seldom realizes that he has done it at all; there are footnotes to show the composite sources but the chapters have all the freshness and distinction of the original papers, and there is no sense of discontinuity where one extract succeeds another. In his choice of material, too, Dr. Denny Brown deserves our thanks; though with him we may deplore various omissions, his selection covers all the major lines of Sherrington's researches, and is constantly reminding us of the wide range as well as the originality of his work.

Sherrington's primary business has been with the physiology of the nervous system, and this volume is primarily a record of his scientific achievements in that sphere. For many of its readers, however, it will be valued even more as the record of a personality, as a record of Sherrington's way of looking at things, of solving a problem and of writing of what he has done, as a study, in fact, of the behaviour of a remarkable individual, 'C. S. S.' All through the book there are examples of the acute observation which finds so much new meaning in a posture of a cat's hind limbs or a flick of its ear, and of the experimental skill with which a complex act is resolved into its simplest components. For it has been Sherrington's achievement to explain the integrative properties of the nervous system by the analysis of such finished products as standing or scratching. But these chapters reveal much more than the method of approach and the technical equipment of a celebrated neuro-physiologist; they show as well the characteristic outlook and characteristic style which lends a peculiar charm to Sherrington's prose and is essential to the complete picture. In the present volume there are abundant examples of the apt turn of phrase, the striking metaphors and sudden illuminating comparisons which enrich his sentences.

We could have wished for more: this, indeed, is our only disappointment, though Dr. Denny Brown is not to blame. We cannot, of course, have a single volume to illustrate the many qualities of one who inspires such high regard and warm affection in all his colleagues. We should have liked samples of his verse, of his reviews and historical or biographical writing to place beside the strictly scientific papers. In his preface, Dr. Denny Brown lists some of the extracts he would have liked to include. The list is tantalizing, though it does not diminish our gratitude to the editor for what he has done. The testimonial he has given us is worthy of the great man of science to whom it is addressed and will certainly induce the reader to sample 'C. S. S.' in his other moods.

PROBABILITY AND ITS APPLICATIONS

Probability, Statistics and Truth

By Prof. Richard von Mises. Translated by J. Neyman, D. Sholl and E. Rabinowitsch. Pp. xvi + 324. (London, Edinburgh and Glasgow: William Hodge and Co., Ltd., 1939.) 12*s.* 6*d.* net.

THIS book is scarcely the philosophical treatise which its title may suggest. It is the written-up version of six lectures on probability and applications, as conceived from von Mises' special pragmatic and empirical point of view. The lectures, to each of which a chapter is devoted, are couched in popular and non-mathematical style, but have none of the faults of this style. The English translation is excellent.

Dr. von Mises is well known as a strong protagonist of the relative frequency theory of probability. Probability to him is the limit of relative frequency in an indefinitely continued sequence of trials, but the sequence must be random. Imagine a coin spun repeatedly; write 1 for heads, 0 for tails. Then, according to von Mises, if in n spins m 1's appear, the probability p of heads for this coin is the limit of m/n as n tends to infinity; but he postulates not only the existence of this limit, but also the important additional property, that if any infinite subsequence be lifted out of the parent sequence on the basis of position only, irrespective of whether 1 or 0 appears in that position, then that subsequence shall have the same limit p as before.

Much of the earlier part of the book develops in simple language this theory of random sequences, and compares and contrasts it with the classical theory of probability. The later chapters pass, rather more summarily, to such topics as the so-called 'law of large numbers', kinetic theory of gases, the quantum theory, statistics and causality and the principle of uncertainty. This is all interesting, and done with an original turn, but the mind of the reader keeps reverting, with sympathetic scepticism, to the original attempt to define randomness. How can the postulate of place selection be expressed in mathematical form? We may lay down particular subsequences, for example, those enumerated by the squares of the natural numbers, or by the prime numbers, and so on. These are special place selections, and even for them it will surely be necessary to prove that parent sequences admitting such place selection actually exist. The author assures us that A. H. Copeland and A. Wald have found satisfactory answers to such questions as these.

All the same, to the present reviewer, a von Mises sequence is merely a *sample* sequence, extended to infinity, for the coin or other object, and is only one of an aggregate of sample sequences characteristic of the object. A sample of what? There's the rub; we are brought back to the *a priori*. And why bar the door so strenuously to sequences other than the postulated random ones? Systematic sequences, for example, 010101 . . ., are imaginable, as well as sequences which, in respect of the same coin or object, may not have the same limit *p*. The desirable thing would be to deduce the sequences from *a priori* conditions, and to show that the exceptional ones, which we may, if we please, call non-random (though the concept of randomness becomes unnecessary), are of zero measure in the aggregate of possible sequences.

Such views, which are put forward here for what they are worth, are in no way intended to disparage the book, which is a most valuable addition, from any point of view, to the literature of statistics and probability. A. C. A.

DEVELOPMENT IN ETHIOPIA

Ethiopia
An Empire in the Making. By Ferdinando Quaranta. Pp. xx+120+23 plates. (London: P. S. King and Son, Ltd., 1939.) 7*s*. 6*d*. net.

WE have to go back to the days of Rome for the mode of development inaugurated by Italy in its new Empire of Ethiopia. It started with road-making, on which at one time 60,000 Italians were employed, and already more than 3,000 miles of macadamized highways have been built out of 7,000 miles planned. At the same time the Italian scientific societies were mobilized to collect and tabulate the facts relating to earth, air and water. Lake Tana is stated to be of little importance to the Nile floods. Alluvial gold was discovered and is now being worked, but there is no likelihood of rich reefs. Platinum seems possibly to be of more importance, and there was also discovered copper and iron ores, but no petroleum. The fauna and flora were surveyed in connexion with their adaptation to various altitudes and meteorological conditions.

Meantime, Castellani's wonderful health service of the war had been converted into a permanent organization for the country with a first-class research laboratory adapted to pathology and parasitology at Addis Ababa and hospitals in each of the four provinces which were created; about eight hundred qualified medical officers are employed. Surveying the collected facts, Italy granted twelve billion lire (£133 million) to be spread over some years for special development. Agricultural veterinary and forestry services were established with experimental stations in each province, these governed and manned by university-trained officers. In the civil administration we deduce that the method employed is an army to keep the peace, with specially trained civilians whose duty is mainly the development of the country. There is little information on the administration, but the education and health of the natives seem to be an especial care. Meantime large areas of land in the high plateaux were found derelict, much of it the former property of Ras Makonnen, and steps were taken to colonize it. Upwards of a thousand Italian families have been here settled, growing grain, coffee, cotton and a host of minor products. For some years this immigration may be almost indefinitely increased by the introduction of regular cultivation in place of the alternate clearing and fallowing of the land employed by the natives. To this end a commission is at work investigating titles to land so far as they exist.

The technique of the Italians throughout would seem to be that of a large business firm rather than the haphazard method usually adopted in British colonies, where development is in the first instance confined to what already exists, usually by the increased employment of the old methods. Scientific men are only called upon when some pest appears or there is a shortage of food, the basal facts required for their employ being still unknown. We can recall no instance where the State has boldly capitalized development and colonization, the great settlement hoped for in East Africa at the beginning of the century having degenerated into the formation of large ranches worked by native labour, a condition paralleled all the way south to the Cape. Here in Ethiopia, if success be ultimately achieved, may be seen the commencement of a planned "Dominion" rather than a "Colony", the successful result of which would be of profound world importance. J. S. G.

GEOLOGICAL RESEARCH IN CHINA

The Geology of China
By Prof. J. S. Lee. Pp. xv + 528. (London: Thomas Murby and Co., 1939.) 30*s*. net.

THE remarkable growth of geological knowledge concerning China commenced with the foundation of the National Geological Survey, under the able directorship of the late V. K. Ting, in 1915. Its unbroken series of publications appeared in 1920 and those of the Geological Society of China in 1922. The first volume of A. W. Grabau's "Stratigraphy of China" was issued in 1924, the second in 1928, but invaluable as this exhaustive compendium was for a time, it soon became out of date as new results were accumulated, mainly by Chinese geologists whom Ting and his associates had trained. As the years passed, contributions rapidly increased, for provincial surveys, universities and foreign authors of many nationalities added their quota to the literature.

A new summary was overdue and it has been admirably accomplished by Prof. J. S. Lee, himself a pioneer of the new movement. The book is not, as its title might indicate, a text-book of regional geology of the stereotyped kind: it is rather a collection of essays, planned on a common 'structural' basis, in which all the essential facts are incorporated and their significance exposed.

In the successive chapters of Part 1 the following topics are discussed: the natural physiographical units of China and adjoining territories; the rocks of its ancient floor; its marine transgressions with the succession of their sediments, their characteristic fossils and the chronology of their movements; the geotectonic aspects of the Cathaysian geosynclines and geanticlines, as well as the history of the east-west fold zones which interrupt them at regular intervals. Descriptions of certain types of shear-forms and of their influence upon the existing framework of eastern Asia follow. Studies such as these, continental in their scope, lead naturally to wider inquiries still, and Chapter viii contains an analysis of the facial traits of the earth as a whole, to which is added an exposition of the author's views on the origin of tectonic movements and marine transgressions in general. These, advanced in logical sequence and entering into controversial geodynamical problems, evade abridged treatment and are best considered as a whole. Certain notable conclusions, however, are briefly stated as follows:

> "All tendencies to shearing movement on the continents are to be reduced to two components: the one towards the equator and the other towards the west. The latter is more pronounced in, if not restricted to, the low latitudes" (p. 351).

This, as the author admits, "sounds strikingly Wegnerian". Again:

> "As a whole, then, the surface strain of the earth can be explained by an adequate increase of rotational speed" (p. 358); and
> "The data thus assembled, when correlated with the 'pulsations' of A. W. Grabau . . . seem to favour the conclusion that it is the continued contraction of the earth that has caused the increase of its rotational speed" (p. 364).

These forcible speculations add value to and widen the appeal of the work as a whole, which still remains the only available, concise review of geological research in China as it stands to-day. Prof. Lee has succeeded in the extremely difficult task of condensing into comparatively little space a great amount of widely scattered stratigraphical and structural information, without sacrificing a lucid continuity of style for the sake of brevity.

Part 2 contains two chapters only, one of which is devoted to the contentious problem of China's Pleistocene climate. The other is headed "Regional Stratigraphy", and in it the larger stratigraphical units of fifty-one separate areas, ranging from Jehol and the Inshan Range in the north to Kuangsi and Kuangtung in the south, from South Manchuria and Chekiang in the east to Kansu and Yunnan in the west, are tabulated in natural successions with short lithological details and lists of leading fossils. How far the omission of subdivisions, and in rare cases of even larger units, is justifiable on grounds of simplification is a matter of opinion, but such arbitrary classifications are rarely entirely satisfactory. This one would have been improved by explanations of the origin of the terms and by the insertion of co-ordinates of the localities mentioned. As extensive tracts in China still await survey, modifications of the lists may be anticipated in future editions.

Each chapter is followed by its own selected bibliography, which would have been more serviceable had numerical references been given in the text and index. Illustrations total ninety-three items, including maps, sections and half-tones.

Geologists concerned with the great problems of continental movement will peruse the book with advantage; for students of Asiatic geology, whether their work or only their inclination leads to the East, it is an indispensable guide.

J. COGGIN BROWN.

ELECTRONIC MUSIC

By Dr. L. E. C. Hughes,
Imperial College of Science and Technology, London

By electronic music is meant the electrical reproduction of musical tones through loudspeakers, the actuating currents either having a purely electrical origination, or, if arising from a musical source, depending essentially on electronic means for their control and amplification, thereby leaving the musical designer free to make experiments which are not limited by the necessity of making adequate acoustic power.

Representative Electronic Musical Instruments

Type	Name	Basic principle	Note operation	Special effects	Tone Registration
Novel	Thérémin	Beat oscillator	Hand-adjustment	Glissando, Tremolo, Stop-button	None
	Martenot	Beat oscillator and filters	Hand in ring Keyboard	Glissando, Tremolo Tremolo	Stop keys
	Trautonium	Neon relaxer with formants	Wire over plate	Glissando, Tremolo	Continuous stop knobs
	Novachord*	Valve oscillators with multivibrator division and filters	Keyboard (72 notes)	Mixed Tremolo, variable attack and decay	Dial stops, foot sustain
Piano	Miessner or Vierling	Hammer on strings E-s pick-up	Piano keyboard (88 notes)	Swell and filters	Stop keys
	Neo-Bechstein*	E-m pick-up		Swell	None
	Pianotron*	E-s pick-up		Volume control only	None
Organ	Orgatron*	Air-blown reeds, E-s pick-up	Manuals, pedals, swells, tremolos	—	Stop keys, pistons, and couplers
	Coupleux	Valve oscillators and filters		—	
	Hammond*	E-m generators, synthetic		Variable stops	
	Midgley*	E-s generators, synthetic		Variable stops	
	Electrone*	E-s generators, synthetic		Synthetic bells	

Instruments marked * are easily available in Great Britain and have been examined by the author. All instruments, except the Pianotron, have foot-swells; the organs, except the Hammond, have grand-swells also. In the Hammond, one stop only on each of the manuals and pedals can be drawn at a time. Specifications of organs can be varied over a wide range, according to requirements; the Hammond and the Novachord alone are mass-produced, and therefore invariable.
(E-m = electro-magnetic, E-s = electro-static)

The most comprehensive developments have taken place in the United States of America, where Benjamin F. Miessner and Laurens Hammond lead the patent and commercial fields, and Lee de Forest demonstrated an electronic organ, one valve for each note, so far back as 1915. Germany, France, and Great Britain have also made important individual contributions, and the literature of the subject grows apace. This article is a brief review of the important electronic instruments available in Great Britain. The accompanying table gives the characteristics of a representative selection of such machines, without attempting to be exhaustive, because of the rapid developments in this field and the repeated introduction of new types. Those with novelty value do not compete among themselves, like the pianos. There is certain competition among the organs, since they have all been highly developed to meet a common need. Comparisons are difficult, since one cannot get them in pairs for a proper trial, but probably the time is coming when a scientific assessment of their qualities is due, which would settle many contentions among organists. Technically speaking, no one is quite certain what organists really want.

There are three major aspects of the problem, commercial, scientific and artistic. The commercial drive incites people to want something new or to do something already satisfactory in a cheaper or simpler way, for example, reducing the cost and bulk of pipe-organs, a lighter substitute for bells, or more noise from the feeble harpsichord. The scientific urge is to do these things in a new way, producing perhaps novel effects which may or may not have an eventual commercial value. The artistic aim in supporting these endeavours is to obtain new methods of expression and to compose for them, since composition in orthodox modes seems to be declining. The usage of an instrument depends on whether it is commercially satisfactory at the price, and on the sales drive to satisfy a manufactured demand.

The instruments mentioned have had some circulation and demonstration. The Electrone has been well received in cinemas and by the British Broadcasting Corporation, while the Hammond* has become best known. In the few years that the latter has been available, about four hundred models have been sold in Great Britain as compared with some six thousand in the United States, the production being fifty to sixty a week. Of the other organs, the Orgatron was used at the last Eisteddfod, and the Midgley* has just been launched. The Pianotron has recently appeared, made both by Everett and Chappell, and meets the modern need of conservation of space combined with concert-grand tone and volume. The latest instrument, the Novachord (a Hammond product), is so entirely novel, except its ordinary keyboard, that it will keep musicians of all grades amused for a long time. It is the sort of machine from which any keyboard enthusiast can get something worth while; it does not demand the discipline of the piano or regular organ.

THE NOVACHORD

Of the instruments offering novelty value many have been described, using a great variety of physical effects for generating and synthesizing desired or new musical tones. Valve oscillators, either pre-set or beating, have frequently been employed; also blocked-out wave-forms, either sinusoidal, chopped, or obtained from recordings of high-grade musical instruments, on spinning disks, scanned by light falling into a photo-electric cell, have been used.

The Novachord uses valves entirely, and in a new way. It is the second musical machine put out commercially by Hammond, and we are told there are more to come. It cannot replace any existing instrument, although it can imitate passably many familiar timbres. It has a 6-octave keyboard, above which is a row of stop-lever controls; for the feet there is a swell pedal, a duplicated sustaining pedal, and a bass sustaining pedal. The omission of the pedal clavier is a good selling point for non-organists. The keyboard manuals are not strictly percussive, as in a piano, but by setting the controls for a long build-up time, a very effective percussive touch is obtained, permitting, for example, a legato violin solo with a light harp-like accompaniment, passing through each other, if desired, on the one keyboard. The pedal sustains the weaker notes, without altering their loudness level.

The tones are obtained from twelve oscillators, the frequencies of which correspond to the top chromatic octave, the highest fundamental frequency being $E = 2637{\cdot}0$ ($A = 440$). The remaining fundamentals are derived from these twelve frequencies by division, one half in each of the five stages, each in a multivibrator dividing circuit, rather like those in television scanning circuits. Each fundamental has a control valve in which the output wave-form is adjusted, together with its attack and decay. The 72 notes, therefore, require 144 valves; some channel-amplifiers and power-packs bring the normal total to 159, double-triodes and small pentodes forming the majority. It is claimed that all valves, except the output stages, are lightly loaded and that the valve hazard is greatly diminished. The scheme for frequency-division seems logical, since the top frequencies cannot require much harmonic development; also the tuning operation on the top notes makes for precision over the whole range. Tuning is effected by adjusting the oscillators until one of the divided frequencies beats a known frequency with a known harmonic of the rectified mains.

The basic qualities of the Novachord are in the great range between percussive and singing, and in the adjustable attack. The tone-controls and filters, all adjustable over a wide range, are to some extent what one might expect, leading from a full diapason, reminiscent of a cathedral when fully delayed, to a thin reedy wood-wind of considerable power. Brassy and delicate tones are available, and the string tones are better than have been previously heard on a non-string instrument. A guitar effect is easily obtained, but, what is more interesting, good imitations of clavichord and harpsichord can be found, with, of course, ample volume; such possibilities may help to revive the interest in the older keyboard music, especially in public, which must have waned to some extent because of the lack of acoustic power and the difficulty of the cramped keyboards in authentic models.

A new feature in electronic music is not so much that three degrees of tremolo are here available, but that there are also six different rates, distributed in the twelve oscillators. The result is a delicate shimmer rather than the usual throb or wobble, recalling *tutti* violins; perhaps this is an effect organists are seeking; they never seem certain whether they require amplitude or frequency modulation, or both.

---

* Descriptions of the Hammond and the Midgley organs appear in a paper recently issued by the Institution of Electrical Engineers, to be printed later in the Institution's *Journal*, entitled "Electronic Musical Instruments and the Development of the Pipeless Organ", by G. T. Winch and A. M. Midgley.

In construction, the Novachord has novel features. The whole of the valve system, couplers, filters, etc., is built into an enormous chassis, which can be turned over for servicing; electrical connexions to the keyboard are taken through long springs, so that the valve system need not be made dead during adjustments.

Finally, it may be remarked that there is no synthesis of notes on an equi-tempered scale involving borrowed quasi-harmonics, as in some electronic organs. This may please regular organists, because the non-coincident harmonics of the notes of a chord beat against each other in the customary way, and are not resolved into a perfect series of overtones, which is apparently one of the things conservative organists do not like, however pure it may be declared to be. We refrain from attempting to define what a pure tone, in the musician's sense, is supposed to be.

NEW PIANOS

The difficulties of imitating a piano are great, the initial impulse and the dither being awkward from the electronic point of view. A negative time-constant of attack has been achieved in the Novachord and this may lead to a complete electronic piano. The electrical amplification of piano tones is of long standing, but the usage has been slight; the recent arrival of the Pianotron may change this.

It is an easy matter to apply either electromagnetic or electrostatic pick-ups to the strings of the piano, and to control the output currents in volume and tone; the mistake which seems to have been made is to try to get something new out of hitting a stretched string with a felt hammer. It is true that tone amplification permits less tension in lighter strings and the elimination of the sounding board, with consequent lighter frames and extremely long time of decay, due to reduced damping. In the Neo-Bechstein, the middle forty notes alone have double strings, the remainder are single. This results in a steel-string tone, substantially undamped when sustained, with great range of crescendo and diminuendo on the swell pedal. Supposing that one wants real steel-string tone, very great care is necessary to avoid considerable blur. This instrument uses electromagnetic pick-ups, one for each set of four strings, located near the ends of the strings remote from the hammer. In the Vierling Electrochord there are a number of pick-ups along the wire, so that some of the sustained overtones are not lost.

Whereas in the Neo-Bechstein the piano has been simplified, in the latest Pianotron, where only straight amplification with electrostatic pick-ups is attempted, it has been found that it is essential to take the greatest care in the construction of the complete small piano, otherwise defects in the tone production are magnified. The electrostatic pick-ups are merely adjusted screws, ranged on a shaped board, which can be fitted into any ordinary piano: screening to some extent is essential, but the scheme permits concert-grand volume in the smallest space at a very reasonable cost. Many novelties may come and go, but the attractions of the dynamics of the free felt hammer on trichords will remain for those who wish to attain to them.

PIPELESS ORGANS

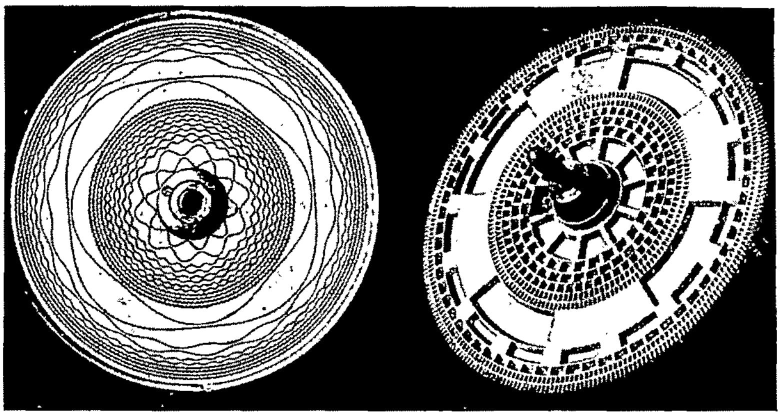
The dictionary definition of an organ must now be curtailed by the omission of any reference to pipes blown by air, for clearly an instrument which is played like an organ and sounds like an organ is certainly an organ, in spite of the purists. The wide variety of wave-forms obtainable from a valve oscillator has induced inventors to synthesize and control tones for organ purposes in diverse ways; the more recent successful instruments, however, do not use valves at all, except for amplification.

The Orgatron is most near a regular organ; indeed, it is a five-rank instrument, entirely pneumatically controlled, with air-blown free reeds, the motions of which are amplified through electrostatic screw pick-ups. The scheme is rather like that of the Pianotron, except that the polarizing voltages are not constant but are applied to the ranks as required by the stop keys. Fundamentally, when a key is depressed, high-pressure air is passed into the tube mechanism and eventually allows low-pressure air to pass through all reeds brought in by the pneumatic action of the stops. The stops also charge the pick-up screws to pre-set potentials through resistance-capacity retarders (to obviate key clicks). The fluctuating potentials on the screws, arising from the motion of the reed and consequent change in capacitance, are applied rank by rank, all the rank screws being in parallel, to the relative amplifier, after which they are mixed by anode-coupling.

Thus there is no synthesis of tones in the electronic sense. The five ranks of reeds, of which there are 289 in all, are voiced and tuned by the usual manipulation of the languids, and fundamentally give celeste, melodia, diapason, viole, and a pedal tone. From these a good selection of registrations is possible, augmented by a synthetic oboe and quintadena. Actual tubular chimes can be operated by second touch on the great, and an echo-radiating unit helps with reverberation in damped surroundings. Tremolo arises from a motor-driven paddle in front of the loud-speakers.

In appearance, the Orgatron is similar to most other two-manual organ consoles.

The Hammond organ has previously been described in these pages (Nature, June 19, 1937, p. 1043), and was shown by Sir James Jeans recently at the Royal Institution. The original model has been brought into conformity with the requirements of the Royal College of Organists for non-secular purposes by curving and adding a few notes to the pedal clavier, by having independent swells for the two manuals, and replacing the manual stop keys by pistons. Readers will remember that tones are synthesized from 96 inductor generators on two shafts driven by a synchronous motor, a number of adjustable stops for experimentation being provided.



The Compton electro-static frequency generator.

Left, one of the stators, showing the electrified tracks between anti-phase sine-wave insulating ridges, the remaining spaces being earthed; right, the rotor, which scans all the tracks and couples the modulated potential to the grid of the amplifier via the ball-bearing contact at the end of the shaft.

Scientifically, the Electrone and the Midgley are very similar. Each uses electrostatic runners, the periodic change in capacitance modulating the potential steadily applied through a resistance. In the Electrone there are twelve generator units, corresponding to the lowest chromatic scale, driven by one continuous belt from a synchronous motor. In the generator unit the scanner is connected, together with the eleven others, to the grid of the first amplifying stage. The radial scanning blocks, one per wave-length, are embossed so as to oppose double sine-wave tracks with earthed separations.

It is evident that all the harmonics of a bass-note can be obtained from one unit, since there is no fundamental difficulty in cutting tracks of an increasing number of wave-lengths. The total number of tracks is, however, markedly reduced by borrowing. For example, on the natural scale the *G*-wheel has a speed 1·5 times that of the *C*-wheel, all the units being the same, except for speed. Therefore the 3rd harmonic of *C* coincides with the 2nd harmonic of *G*; so why not use the 2nd harmonic track on the *G*-wheel when the 3rd harmonic of the *C*-wheel is required, thus dispensing with the 3rd harmonic track on the *C*-wheel, and so on, yielding a great economy in tracks? The driving wheels, however, are so diametered that the fundamentals and the harmonic tracks are equi-tempered. This makes the *G*-wheel about 0·1 per cent slow on the *C*-wheel. The third (borrowed) harmonic of *C* is therefore a little out of tune, a fact which is easily noticed on a cathode-ray tube, but it is doubtful if any organist can have noticed it by ear. Again, when *C* and *G* are sounded together, either on the keys or as a synthetic stop, the third harmonic of *C* does exactly coincide with the second of *G*, since it is borrowed, the increased magnitude of the common frequency being provided for in the electrical circuits. This means that the beat which ought, on the equi-tempered scale, to be present between the third harmonic of *C* and the second harmonic of *G*, amounting to about 0·1 per cent of the nominal common frequency, is not there. This argument can be greatly extended, the absent beats between some harmonics being more pronounced than that above indicated. The Electrone compromises in that only the third harmonics are borrowed.

There is no doubt that the scheme works and the machine sounds very much like a regular organ, but is it this absence of beats among harmonics which prevents the more precious and conservative of organists from admitting that the Electrone is an adequate substitute, at a third the cost, for a regular pipe-organ? Can any ears be so sensitive in a live room?

The Midgley electronic organ functions in a very similar way, except that in the unit generator the dielectric alone rotates. The sine-wave areas on the stator electrodes oppose the blocks of the scanning dielectric as before. The notes are synthesized as required by the stops in the electrical circuits as before; registering a number of stops builds up the contributions, just as extra ranks of pipes are ordinarily brought into action. Corresponding in function to the draw-bars in the Hammond, sets of dials are provided for players to experiment with in using new stops or doubling existing stops.

It can be fairly claimed that these electronic organs function as intended, but whether one is superior to the others for a specified musical purpose is an open question and must await a proper series of trials, with adjudication by a representative body of musicians; meanwhile, those who have to pay for organs are deciding for themselves.

Accepting the musical adequacy of electronic organs, their use in churches has several artistic and technical advantages. The disposition of the sound radiators permits a fine unanimity of attack in congregational singing. Acoustical treatment to enable preachers to be heard need not spoil reverberation, which can be increased artificially to any degree desired. Finally, the great enemy of pipe-organs, cold weekdays and a warm Sunday, is rendered innocuous: electronic organs scarcely need tuning.

The craft of the organ tuner, with his mallet and cones, has started to pass; he is being replaced by an electrician, with no more equipment than is required for servicing a radio-set. There is one thing we can be certain of, no electronic organ ought to succeed unless it is finally voiced by a craftsman of tradition. If this is not insisted on, classical organ tone will not be known to the rising generation, brought up on secondhand and harsher music, and may be lost for ever.

APPLICATIONS OF PSYCHOLOGY IN WAR CONDITIONS

A SYMPOSIUM on some applications of psychology in war conditions was arranged by the Industrial Section of the British Psychological Society and held on January 25. The introductory paper was by Dr. May Smith, who gave an outline of the final report of the Health of Munition Workers Committee, published in 1918, and addressed to the Right Hon. Winston S. Churchill, M.P., then Minister of Munitions. The Committee included Sir George Newman, Sir Walter Fletcher, Sir Leonard Hill, representatives of the Home Office, members of Parliament, physiologists and pathologists. It had been appointed in September 1915 "to consider and advise on questions of industrial fatigue, hours of labour, and other matters affecting the personal health and efficiency of workers in munition factories and workshops".

At the beginning, the Committee was confronted with the width and complexity of its inquiry. The central and foremost problem was concerned with fatigue. Having realized that continuous human activity is associated with a gradually diminishing capacity, the Committee decided that the only direct test was that of output.

Views on the more theoretical aspects of fatigue were really immaterial, since it was known that the ordinary restrictions on hours of labour had been very widely relaxed, that Sunday labour previously forbidden for women and young persons and practically unknown for men, except for a few continuous processes, had become common. The employment of men for 70–90 hours a week was common, more than 90 hours was not infrequent, and there were even cases in excess of 100 hours. In short, there was a return to some of the worst conditions of the early nineteenth century.

The Committee used two methods of getting information: (1) it took evidence from people in direct contact with workers, (2) it initiated *ad hoc* investigations. The first method enabled it to get information at once, the other necessitated time.

On reading through the evidence, it is impossible not to be struck by the volume and pertinence of the findings. On the whole, the evidence showed that long hours imposed too severe a strain on the workers, with the result that the rate of production tended to decrease, sickness absence and broken time to increase. Evidence of the almost intolerable strain on the management was given. The full blast of the hours was not felt at first, because the increased pay resulted in better food.

Such evidence, while overwhelming in some cases, was, however, not quantitative, and witnesses differed widely as to what constituted reasonable limits; the Committee had to emphasize the almost complete absence of any scientific data.

The appointment of Dr. H. M. Vernon and others was intended to supply this deficiency. He showed by output figures that the 12-hour day was a costly and useless procedure, that the long hours simply defeated their own end. "The country cannot afford the extravagance of paying for work done during incapacity from fatigue just because so many hours have been spent upon it," reported the Committee.

Apart from hours, environmental conditions were realized as important, and ventilation emerged out of the hands of the engineers and passed to those of the physiologist, and under the ægis of Sir Leonard Hill there entered the katathermometer.

Lost time through sickness absence, lateness, broken periods, or just absence, soon became a formidable problem. The causes of lost time were classified into two main groups : (*a*) Causes mainly inherent ; for example, the employment of people of inferior physique, inadequate housing and transport facilities, wintry weather, darkened streets and inequalities of food supply, the domestic duties of married women, the war-preoccupation and exigencies of all workers, sickness and disease caused by conditions outside the factory. (*b*) Causes mainly controllable ; for example, fatigue, sickness and accidents of factory origin, insufficient wage incentive, faulty internal organization, indifference, slackness, laziness, discontent, prolonged hours, overtime, insufficient rest periods or holidays, and excessive consumption of alcoholic beverages.

The Committee came to the conclusion that the absence through sickness was considerably underestimated, and pointed out that if there is an undue proportion of sickness in any group of workers there is also likely to be lessened vigour and activity among those who are not away sick. It noted the absence of adequate records, partly due to difficulty in regard to medical certificates and partly because minor illnesses were not reported.

The section on incentives starts off, not with wages or bonuses, but with the statement that "the first incentive is the health and physical fitness of the worker", and although the Committee confined itself to the factory conditions contributing to that, yet the field covered is very wide. Only after this does the Committee discuss wages, which must be "well adjusted, equitable and clearly understood".

The Committee notes that "what is needed is not a cast-iron system of employment but a sympathetic or correct understanding of the physical and mental capacities of each worker and their most satisfactory and economical application".

The present War has introduced many of the conditions of the War of 1914–18, but already after four months there are signs of an interest not aroused until after thirteen months before ; happily we are better equipped now than in 1914.

Dr. Vernon took up the discussion, pointing out that excessive hours constitute a major problem when increased output is urgent. Many employers cannot grasp the fact that, after a certain number of hours of work, the worker is so fatigued that production falls. Some investigations undertaken during the War of 1914–18 showed that the actual gross output—not merely the average hourly output—is less on a 12-hour day than on a 10-hour. It is true that in the early stages of a war, patriotism plays a definite part in keeping up the output, and in the last War employers often defended the excessive hours on these grounds ; but Nature cannot be defied indefinitely and many men and women were in a chronic state of fatigue. For many processes in munition work, Dr. Vernon found that output is a very satisfactory measure of the effects of hours of work, since the same materials are being used and the same articles made, the only important variable being the number of hours worked. Sunday labour, except for emergencies, proved wholly unsatisfactory, in spite of the extra pay : it has been described as "8 days' pay for 7 days' work with 6 days' output".

The problems involved in night-shift work are not easy to solve, for, quite apart from the organization within the factory, there are complications connected with the domestic arrangements of the workers and transport.

With regard to the material environment, Dr. Bedford pointed out that there is now available considerably more scientific knowledge than in 1914. Numbers of researches have been made to find out the relationship of lighting, heating and ventilation conditions to efficiency, comfort, accidents, and health. The last twenty-five years have shown a pronounced tendency to have more light, not only for fine work but also in general : a good light is felt to be more cheerful. Working all day in artificial light gives people a feeling of being cheated ; if, however, owing to the nature of the work, this is inevitable, much can be done by the use of extended light services and by arranging artificial windows and similar devices.

Heating and ventilation cannot be kept separate. It used to be considered adequate if the air was pure and stimulating : now increased emphasis is laid on the need for an adequate degree of warmth as well. As with lighting, the standard of warmth has gone up ; many factories used to be below 50° F., whereas recently a research worker experienced difficulty in finding one below 55°. For the full assessment of thermal conditions a single yardstick, however, is impossible ; individual conditions have to be considered and weighed.

The recent 'black-out' regulations have added to the difficulties of factories relying on open windows, so that there are many complaints of stuffiness and overheating. Forms of light-traps, however can be devised, which allow of the entrance and exit of air while complying with the lighting regulations.

Dr. Millais Culpin said that since 1914 considerable progress has been made both in the diagnosis and treatment of psycho-neurotic illness. The last War took us unawares, with few doctors capable of treating such illness or even of recognizing its existence. Psychological casualties in the civilian population under direct war risk may be fewer than we might expect, for the civilian is allowed to show manifest fear or to run away. That some kinds of psychoneurotic people should retire to the West Country—as many did during 1914–18—is best for everybody. He regretted the use of a phrase now rather popular, namely, 'fright neurosis'. Fear is of biological significance, and to be afraid, even greatly afraid, is, in some conditions, a natural reaction. Pathological fear is in a very different category, the reaction being usually quite inadequate to the situation.

Nor is it right to class all psychoneurotics in one group; some of them can be diagnosed as likely to break down in peace or war, and some will not; others will withstand the most difficult conditions. Some who had managed to adjust themselves to the last War and to the years since have broken down now, suppressed memories of the last War being touched up. To confuse such cases with 'fright neurosis' is disastrous.

How civilians will behave in air raids is difficult to predict. It is possible that some with a high degree of claustrophobia will prefer to be bombed rather than have the feeling of being in an enclosed space; within a shelter some may faint, and others may adjust to the circumstances although feeling considerable discomfort. With regard to the question of what can be done with cases of uncontrolled behaviour or of those who faint in an air-raid shelter, Dr. Culpin said that the fainting neurotic might be left to himself, while harsh treatment might be needed for others. Two schools exist in the medical profession with regard to the treatment of the neurotic who has broken down: one is the school which would diagnose and treat by psychological means, and the other he called the 'kick in the pants' school. Fortunately for the world, the latter is found chiefly among the elderly, who are despised by the younger and more adequately trained doctors.

Mr. Alec Rodger, discussing the selection and grading of personnel, said that a great stimulus to this was provided by the Americans in the War of 1914–18. In order to sort out people fit for different kinds of training, nearly two million men were given intelligence tests. The experiment proved so successful that other countries, including Germany and the U.S.S.R., have adopted similar intelligence testing procedures. Mechanical aptitude tests have also been widely employed. Both intelligence and mechanical aptitude tests and other psychological techniques are used to a limited extent in our own fighting Services.

The value of tests in the grading of personnel needs special emphasis. Many are accustomed to think of them only as instruments in the selection of men and overlook the fact that they can be used effectively in the grading process, the aim of which is to arrange that individuals of similar abilities are instructed together. Mr. Rodger added that, since intelligence tests had been used by many school and other authorities over a period of years, much data of value to the Services could probably be made available immediately.

CENTRAL REGISTER OF SPECIALISTS

(SECTION FOR SCIENTIFIC RESEARCH)

IN the issue of NATURE of April 8, 1939, p. 575, there was an account of the establishment by the Royal Society and the Ministry of Labour jointly of the Central Register of Specialists (Section for Scientific Research), with the main aim of providing a list of scientific workers whose professional services might be useful in time of war. It will be remembered that each scientific worker was asked to fill in a card giving an account of his qualifications and some details of his career. From the point of view of the Royal Society the register also had a secondary purpose, for, if there were not to be a war, then it was felt that this was a good opportunity to obtain a census of the scientific knowledge of the country which would be of general value. With the outbreak of war the main purpose of the register was called into play, even before its compilation was complete, and it will be of interest to give a short account of some of its consequent workings. This article only deals with the register of men of science, and does not touch on the similar work of the Ministry of Labour in other branches of learning or technology.

In the spring of 1939, cards were sent out to men and women whose names had been furnished by certain learned societies. Up to the end of July a little short of eight thousand had been sent out and some five thousand replies received. Since July, several hundred more have been sent out to people who had been missed in the earlier lists, and the total number of cards returned is now more than six thousand. This list is largely composed of names from universities, from industries and from the research associations. Men already in the Government service have also been permitted to send in their cards, so that they are included in the census; though of course their services are already at the disposal of the Government, so that for them the more immediate function of the register does not arise. The committee of men of science which is helping to work the register is subdivided into panels composed of experts in each subject, and during the summer the panels met to sort out and classify their cards. There are, of course, great differences in the characters of the various subjects, and there was great uncertainty in the natures of the expected demands, and so no uniformity was attempted in the practice of the different panels. For example, the engineers and physicists subdivided their list into quite small groups, whereas in mathematics it was inappropriate to do this because, apart from the leading experts in each branch whose names would be well known, general mathematical skill is easily transferable from one subject to another.

On the outbreak of the War, the register immediately began to function. A certain number of leading men of science had already been earmarked for service directly, so that it was for junior posts that the register was specially useful. Recourse to the register is now the normal procedure for filling all scientific posts in the Government service when these are of the standard of the register. The way the register operates is usually somewhat as follows. The Government department requiring staff presents a written demand to the register for the staff that is needed in order to fill a certain number of posts, stating the nature of work, the qualifications required and the salary offered. A preliminary selection from the cards in the register is made by the staff of the Ministry of Labour with the advice and assistance of the expert panels, and often of technical representatives of the departments. The selection is then submitted to the appropriate panel so that the selections can be considered, and if necessary discussed with a technical representative of the ordering department. In this way the quality of the man needed can be more accurately assessed. When a final selection has been made, the men selected are circularized and are asked whether they are willing to be considered for the post offered provided that their employers are willing to release them. Thus the department concerned receives from the register what is practically a short list of suitable candidates who are known to be willing to take the post offered. The department then itself arranges for interviews and makes the appointments, and the Ministry of Labour takes no further part in the proceedings, except to record appointments.

It may be appropriate here to refer to a matter which has received some attention though it is not directly connected with the register. In many laboratories a number of men are doing co-operative research, and it was felt that the operation of the register, which deals with individuals, might seriously endanger such work by taking away some members, possibly even though they might be only minor members, of such teams. The question of safeguarding scientific teams was entrusted to the Department of Scientific and Industrial Research. The matter proved by no means easy, because a team is a very indefinite thing. For example, in one university a laboratory might with equal justice be regarded as either one or several teams, while in another, with quite as good a scientific record, the work of the members would be so independent that it would hamper their usefulness to call them a team at all. In the end it was settled that (with one or two special exceptions) there were to be no teams in universities, since if the operation of the register was in danger of spoiling important team work it would be easy for the university or the head of a department to make (as 'employer') representations to that effect. On the other hand, there was danger that the production of industry might be seriously hampered by draining away the members of its research teams, and so the research laboratories of a number of firms have been registered as teams. Their members cannot be called on through the machinery of the register without consultation with the Department of Scientific and Industrial Research.

The register has now been working for more than four months and it is possible to review some of its results. It appears that it has well justified the effort put into its preparation. For the most important appointments it was of course scarcely necessary, as the likely candidates for such appointments would be familiar to any adviser, but for other appointments it has been most useful, so that wherever a need has arisen in the Services, names could be put forward to meet it. In some of the subjects the demand has exceeded the supply, but there are a good many where the opposite is the case. As might be expected, the biological subjects are not in great demand for matters connected with the Services, and few new outlets for them are apparent in agriculture or industry; it looks unlikely that, for example, there will ever be calls for more than a limited number of zoologists or botanists as such. On the other hand, certain categories have become practically exhausted of scientific men. The question of training people for rare categories is being examined, and persons with 'secondary' qualifications in them are used when possible.

Consideration has been given to the point that it is now possible to say that a good many of those on the register who are reserved under the Schedule of Reserved Occupations will probably never be called on to use their professional knowledge for war purposes in a civil capacity, and the possibility has been examined of notifying them that they are released from their reservation. It was felt that it would be very invidious to take the initiative in this, but machinery has been set going to arrange for the possibility of release. It will be open to any scientific man reserved under the Schedule to apply for release, and his case will be considered by the appropriate panel. In arriving at its decision, the panel will give consideration to any representation by the applicant's employer (university, firm, etc.), and to the possibility that the applicant's professional services might be needed later, even though the demand is not yet apparent. In view of the differences of demand in the various scientific subjects, each panel is adopting its own policy, but broadly speaking the general policy will be that release will be granted to anyone who is unemployed or likely to become so, while for others the grant will only be made after much more careful consideration of each application.

OBITUARIES

Sir Francis Goodenough, C.B.E.

SIR FRANCIS GOODENOUGH died on January 11, after a long period of ill-health, at the age of sixty-seven. It is possible to surmise that had he come under the influence of a science master at an impressionable age, as has happened to many of us, he would have made a career in some branch of science which would have gained a great leader. As it was he performed what is perhaps the more difficult feat, namely, the introduction of some measure of planning and science into commerce.

He lived to see the subject of management adorned by the adjective 'scientific' and to participate in international congresses under the double heading. He was one of the first and greatest salesmen in the gas industry, where he emphasized the importance of supplying a service as well as a commodity. Equally valuable were his services in the cause of education applied to gas engineers and gas salesmen. Here he insisted that the scheme, elaborated in conjunction with the City and Guilds of London Institute, should be one of education as distinct from examination only. It is known that the early difficulties in connexion with this were almost overwhelming, and that but for his patience it would have been difficult to overcome them.

Sir Francis was a pioneer of co-operative advertising and a leader of many other co-operative movements both within and without the gas industry. A man of rare vision and large ideas, faculties usually involving impatience, he was characterized by an easy and genial manner and the quality of complete sincerity. In addition to his successful career with the Gas Light and Coke Company, which he saw rise from something very much smaller to its present outstanding position, he was always visualizing developments ahead of the time.

Sir Francis was one of those who will probably appear greater in retrospect than he does at the time of his activities, when personalities and policies hold the stage. Science and commerce lie perhaps on opposite sides of the river of daily endeavour, but many bridges are being built across the river, over which traffic struggles in either direction. One such bridge builder was Goodenough; the edifice he has erected, built on sound foundations, will stand the stresses of stream and wind and the increasing load of progress for many years to come. E. F. ARMSTRONG.

Miss E. K. Pearce

MISS ETHEL KATHERINE PEARCE, whose death occurred on January 8, at Morden, Dorset, at the age of eighty-three, was an entomologist who devoted her energy and enthusiasm almost entirely to Diptera. A daughter of a vicar of Morden, she had around her one of the finest entomological hunting grounds even in a county as favoured as Dorset. The first series of her work, "Typical Flies", a photographic atlas in which the author sought to popularize and extend the study of an order of insects much neglected in those days, was published in 1915. A preface giving practical guidance for collecting and preservation is followed by a sketch of Brauer's classification of the Diptera, and his sixty families are named, the Aphaniptera (fleas) being included. The forty-five pages of reproductions from photographs, considering the great difficulty of such work, are admirable, the flies figured being all recognizable and characteristic. In some cases preliminary stages are shown. The photographs of typical Dorset localities are a very pleasing and helpful feature. They not only give information as to the habitat of the fly, but also tempt the Nature lover to explore such delightful environment.

The flies taken as types of the various families were chosen with the help of the late Prof. Theobald, F. C. Adams, and other capable authorities, with great care. A second series appeared with 125 photographs in 1921, and a third series with 162 photographs in 1928. In all, fifty-five out of the sixty families of flies enumerated by Brauer are represented in the three series by a type fly. The brief biological notes given under the figures add much to the interest of the book. The author was helped, too, in her work by her brother, Mr. N. D. R. Pearce.

Amiable and benevolent, and ever keen on doing useful work, Miss Pearce's death leaves the ranks of entomology the poorer. Her contribution cannot fail to aid beginners in classifying and identifying the flies they find. Non-specialists, also, who wish to place any fly they see in its systematic position, will likewise find Miss Pearce's guide a boon.

F. H. HAINES.

WE regret to announce the following deaths:

Prof. Aristide Busi, director of the Institute of Medical Radiology, Rome, aged sixty-five years.

Mr. W. M. Gardner, principal of Bradford Technical College during 1905–21, on December 22, aged seventy-eight years.

Mr. W. H. Lovegrove, formerly conservator of forests, Kashmir, on January 25, aged seventy-two years.

Prof. Ugo Mondello, the well-known seismologist, formerly director of the Ardenza Observatory, Italy, on December 3, aged sixty-one years.

Prof. S. Lees, Chance professor of mechanical engineering in the University of Birmingham, aged fifty-four years.

Mr. B. D. Porritt, director of research of the Research Association of Rubber Manufacturers, on January 28, aged fifty-six years.

Mr. F. T. Shutt, C.B.E., formerly Chief Dominion Chemist and assistant director of the Central Experimental Farm, aged eighty years.

Prof. C. A. Strong, formerly professor of psychology in Columbia University, aged seventy-six years.

NEWS AND VIEWS

Scientific Collaboration between Britain and France

A DELEGATION from the Centre National de la Recherche Scientifique, led by its director, Prof. H. Longchambon, has been visiting Great Britain during the past week. The other members of the delegation were: Prof. M. Fréchet, professor of mathematics at the Sorbonne; Prof. G. Darmois, professor of mathematics at the Sorbonne; Prof. F. Joliot, professor of physics at the Sorbonne; Prof. P. Auger, professor of physical chemistry at the Sorbonne; Prof. C. Sadron, professor of building legislation at the Ecole Nationale Supérieure des Beaux-Arts, Strasbourg; Prof. G. Dupont, professor of theoretical chemistry at the Sorbonne; Prof. Denivelle, professor of chemistry at the Ecole Supérieure de Chimie at Mulhouse; Prof. A. Mayer, professor of medicine at the Collège de France; Prof. L. Blaringhem, professor of botany at the Sorbonne; Prof. P. Chouard, professor of agriculture at the Conservatoire National des Arts et Métiers; Prof. P. Langevin, professor of experimental physics at the Collège de France; Dr. P. Montel, professor of mathematics at the Sorbonne. This, it may be presumed, is one of the measures referred to by Lord Chatfield when he spoke recently in the House of Lords on the exchange of information and extension of the liaison between the scientific organizations of Great Britain and France (see NATURE, Jan. 27, p. 142).

The programme arranged for the visitors included a reception at the Royal Society on January 29, when the guests were received by Sir Albert Seward and Prof. F. G. Donnan on behalf of the Royal Society. Dr. E. V. Appleton then addressed the meeting, and described the organization of the scientific effort for defence in Great Britain. The French delegation was introduced by Dr. Montel, after which Prof. Longchambon described the steps taken in France to mobilize scientific research for the country's war effort. Prof. Langevin also spoke. On January 30, the French delegation visited the National Physical Laboratory at Teddington, and on the following day travelled to Cambridge, where they saw the Cavendish Laboratory (Prof. W. L. Bragg) and the Colloid Science Laboratory (Prof. E. K. Rideal). A meeting of the Royal Society was arranged for February 1, at which Sir Arthur Eddington was reading a paper on "The Masses of the Proton, Neutron, and Mesotron", and L. Jánossy and B. Rossi a paper on "Photon Component of Cosmic Radiation". Prof. E. J. Williams was giving an account of his experiments on the transformation of mesotrons into electrons (see NATURE, Jan. 20, p. 102), and Prof. P. Auger and Prof. P. M. S. Blackett were taking part in the discussion. On the same evening the French delegation were being entertained to dinner by British men of science.

Scientific Research for the Services

THE Advisory Council of Scientific Research and Technical Development (see NATURE, December 30, 1939, p. 1085) held its first meeting at the Ministry of Supply on January 25. Colonel J. J. Llewellin, in the absence of the Minister of Supply through illness, pointed out the Ministry has numerous establishments for research and development, etc., which, in some directions, work for all three Services: these establishments are supplemented by work in progress at various other research laboratories throughout the country. Lord Cadman, chairman of the Council, said that the research programme is most extensive, comprising more than a thousand items. The subjects being dealt with vary within very wide limits; it is therefore necessary to have an extensive and comprehensive scientific representation on the Council, which will function through a number of committees, on which other men of science will be invited to serve. So far, the committees formed deal with metallurgy, general physics, ballistics, structural engineering, communications, etc. The Directorate of Scientific Research of the Ministry of Supply already has a permanent staff of about nine hundred, but it is satisfactory to know that the Council also proposes to enlist the aid of independent outside men of science if, and when, required.

Institution of Electrical Engineers: Faraday Medal

DR. ALEXANDER RUSSELL has been awarded the eighteenth Faraday Medal by the Council of the Institution of Electrical Engineers. The medal is awarded for notable achievement in, or help to, electrical science or industry, and Dr. Russell is qualified in both respects. His works on alternating currents and the theory of cables have long been classical; not less well known are his researches on the sphere gap, and many other mathematical researches and papers communicated to the learned societies. He recently published the "Life of Lord Kelvin", whom he knew in the early days. Dr. Russell has been connected with Faraday House from its inception in 1889, and became principal in 1909. During fifty years he has helped in, or been responsible for, the training of thousands of electrical engineers, now to be found all over the world. The outstanding feature of this education has been the encouragement of men to bear their own responsibilities; many of his students, both in the early days and recently, have achieved important work even during their student days. He has been for many years a valued contributor to NATURE.

Dr. Russell is a past president of the Institution of Electrical Engineers, of the Physical Society of London, and of the Junior Institution of Engineers. He was elected fellow of the Royal Society in 1924 and made an honorary member of the Institution of Electrical Engineers in 1937. Later in the same year he retired from the more active work at Faraday House and became advisory principal. He thus holds available for the College his life's experience, and maintains contact with the hundreds of old students who can call in to see him, and with the thousands who can only write. We like to think that it is this aspect of his life's work, and the army of valuable men that has resulted from it, that the Council of the Institution of Electrical Engineers had in mind, not less than his mathematical researches, when the award of this year's Faraday Medal was made.

Captain C. W. Hume

CAPTAIN C. W. HUME resigned from the editorship of the *Proceedings of the Physical Society* on January 1, after having been responsible for that journal for a period of twenty years. A member of the reserve of Army officers, he rejoined his unit some time previously, and continued his editorial work until impending changes made it no longer possible. During his tenure of the office, he had seldom missed a Council meeting, and was usually present at science meetings, to obtain a record of the discussion on papers at first hand. He took great pains with the preparation of the *Proceedings* to ensure that papers should be free from ambiguity and obscurity, and printed in uniform style. His other interests were many. He founded the University of London Animal Welfare Society and the Universities Federation for Animal Welfare, and had also taken an active part at one time in the Association of Scientific Workers and the Parliamentary Science Committee, as it then was.

African Studies and the War

NOTWITHSTANDING the War, native administration in Africa must be carried on; and the problems incidental thereto are likely to become more, rather than less, insistent in the world turmoil which now prevails. For the moment, indeed, paradoxical as it may seem, circumstances probably are more favourable to African studies directed to possibilities of future development than if the end of hostilities were within measurable distance. Such, at least, would appear to be the judgment of H.M. Secretary of State for the Colonies, at whose request Lord Hailey will shortly pay a visit to a number of the British dependencies in West, East, and Central Africa to undertake an informal study of certain aspects of native administration. This investigation will carry further the work on such questions which Lord Hailey has already done during his earlier visits, when collecting material for his "African Survey". His inquiries on this occasion, which are expected to take about six months, will be directed in the main to the comparative study of forms of native administration, with special reference to their technical working and their future development. It will be of more than passing interest to see how in the judgment of so experienced an observer as Lord Hailey the diversity of conditions which will be brought under notice justify, or the reverse, the standardization of administrative methods in the interests of native advancement, and how far a more intensive study of native institutions in relation to administration than they have yet received, is demanded.

At the close of his tour, Lord Hailey will spend a short time in Southern Rhodesia, where facilities will be afforded for an unofficial study for comparative purposes of the principles and methods of native administration followed there. This study, it is anticipated, will be of great value when further consideration is given to the difficult questions of native policy in the Rhodesias and Nyasaland, to which attention is directed in the Report of the Rhodesia–Nyasaland Royal Commission (see NATURE, 143, 829; 1939).

International Co-operation and African Studies

INTERNATIONAL co-operation, which in recent years has contributed so markedly to progress in African studies, is now necessarily much curtailed. Nevertheless, the International Institute of African Languages and Cultures, although its existence as an international institution seemed to be threatened, has decided that, so far as possible, its work must continue. In a communication over the signature of Lord Lugard, chairman of the Executive Council, which has been circulated to the members of the Institute, the reasons for the decision are given. Science, it is pointed out, is neutral, and further, the peoples of Africa, in war as much as in peace, need all that science can do to promote their welfare and advancement. "It seems to us important," says Lord Lugard, "that public interest in the welfare of the African peoples should not be 'blacked out' by a too exclusive concentration on events in Europe", adding "we are convinced that the Governments which have accepted responsibilities in Africa will not wish the war to put a stop to the various efforts at the social progress of its peoples, which they have initiated in years of peace." That this view is justified is borne out by the mission undertaken by Lord Hailey at the request of the Colonial Office, to which reference is made above. Further, if the War of 1914–18 may be regarded as a precedent, the problems of native Africa, when peace comes, will not be such as can be solved by improvisation, but only on a basis of the results of carefully digested scientific study over a considerable period.

African Native Institutions and Christianity

A STRIKING instance of the adaptation of African institutions and ways of thought to the promotion of Christianity after intensive study is contributed to the current issue of *Africa* (13, 1, January 1940) by Prof. N. de Cleene. Incidentally, it illustrates the flexibility, to which reference is often made, of Catholic Missions in dealing with native races. In response to a suggestion made by Prof. de Cleene that native art might be of service in the Christianization of Africa, the R. P. A. Walschap, a missionary in the Belgian Congo, made a scientific study of native music and the dance. Being struck by the predominating part played in native appreciation by the element of rhythm, not only did he introduce it into his church services, composing a mass and other music in native style, to be sung to the accompaniment of native instruments, but he also arranged a series of religious dances, in the native convention, for performance at the religious festivals of the Church. The result was a remarkable accession of interest and understanding.

The second example makes use of the graphic arts. The R. P. Vandenhoudt, from the time of his arrival on the Lower Congo some years ago, had made a study of the principles, methods and concepts of native graphic art. He was much struck with native ability in making crude but graphic representations of scenes and events in everyday life. He thereupon conceived the idea of representing scenes from the Holy Scriptures according to native concepts and in native technique. Among a number of scenes to which the method was applied, the most successful, and one which was immediately understood, was the sacrifice of Isaac by Abraham, in which the intended victim was represented according to a native custom, in which the head of a man condemned to be beheaded was fastened to the bent bough of a tree and shot into the air when the fatal blow was struck.

The British Museum (Natural History)

THE important entomological collections, manuscripts, etc., bequeathed by the late William Miller Christy have been received at the Museum. The total number of specimens is 21,312. The collection consists entirely of British Lepidoptera, and includes a large number of specimens which will be of great value as additions to the existing British collection. Mrs. Brownlow, who inherited them, has presented to the Museum a large number of important entomological books from the library of the late Mr. Christy. Further specimens of vanadinite (lead vanadate), including a doubly terminated crystal from Abenab, South West Africa, have been presented to the Department of Mineralogy by Mr. J. N. Justice, and the Department has also acquired two fine specimens of the rare potassium barium zeolite harmotone collected during the summer of 1939 at Ben Resipol, Argyll.

The Trustees of the British Museum decided at their meeting on January 26 that certain of the galleries in the Natural History Museum should be opened to the public on Saturday and Sunday afternoons, beginning on February 3. Much material has been evacuated for greater safety, and many exhibits have been protected in their places in the galleries. There remains, however, a very large proportion of the exhibits in certain galleries, and the Trustees are anxious that the public should have access to them so far as possible. In addition, it is hoped to organize a number of special exhibits of topical interest, about which a further announcement will be made at a later date. The hours of opening will for the present be from 1 p.m. to 4 p.m. (on Saturdays and Sundays only), but the closing hour will be extended as soon as the lengthening of the days and the introduction of summer time make this practicable. Children below the age of twelve will not be admitted unless they are in the charge of an adult, and visitors are requested to carry gas masks.

The Newcomen Society

AT a meeting of the Newcomen Society held at the Institute of Marine Engineers on January 17, Eng.-Capt. E. C. Smith read the second part of his paper on "The First Twenty Years of Screw Propulsion 1838–1858". Having in Part 1 dealt with the work of John Ericsson in the United States, Capt. Smith gave a review of the early progress of screw propulsion in both the Royal Navy and the British Mercantile Marine. The first screw vessel in the Royal Navy was the curious little *Bee* of 33 tons and 10 horse-power built in 1842 and fitted with a side-lever engine driving both paddle-wheels and a screw. The *Bee* for many years was attached to the Royal Naval College, Portsmouth, for the instruction of officers in steam. The first screw man-of-war in the Navy was the sloop *Rattler*, the trials with which in 1844–45 led to the screw being adopted for practically all naval vessels. By 1850 there were about forty screw ships in the Fleet, by 1858 and about 350. Generally speaking, in the larger wooden ships the screw was regarded as an auxiliary and was fitted so that it could be lifted out of the water.

The first mercantile screw vessel to make a sea voyage was the *Novelty* of 1841. The famous iron screw ship *Great Britain* was laid down in 1839 and completed in 1845. She was the first screw ship to cross the Atlantic, but a regular service to America by iron screw ships was not started until 1850, when the *City of Glasgow*, the first ship of the old Inman line, made her appearance. The year 1850 also saw the mails sent from Plymouth to the Cape for the first time by steam. Quite small iron vessels were used, and some of them were fitted with Joseph Maudslay's feathering screw. By January 1, 1857, the Board of Trade register included about five hundred screw-driven vessels, nearly all of them being constructed of iron. A second paper read at the meeting was by Mr. A. S. Davies, and consisted of some extracts from the ledgers of the Coalbrookdale Company relating to castings for Newcomen engines between 1717 and 1769.

X-Rays in Industry

METHODS of utilizing X-rays in industry were discussed in a lengthy paper by Mr. H. P. Rooksby, of the Research Laboratories of the General Electric Co., Ltd., in a paper read before the Royal Society of Arts on January 17. The methods of utilizing X-rays fall into two groups which depend (*a*) upon their power of penetration through various materials, and (*b*) upon their reflection by the regular arrangement of atoms in crystalline substances. The varying resistance of materials to penetration by X-rays enables a kind of density picture of a complex object to be obtained by irradiating the object with X-rays and examining the emergent beam by means of a photographic plate or fluorescent screen. This use is widely known.

Another use for X-rays concerns the continuous series of solid solutions formed by luminescent zinc/cadmium sulphides. Members of this series are used extensively in the manufacture of the screens of the cathode ray tubes, and for colour modification of certain mercury vapour discharge lamps. New fluorescent colours are often obtained by blending two zinc/cadmium sulphides of different compositions. A chemical analysis alone will not reveal when this has been done. The X-ray method enables the composition of both phases to be determined, as each phase will show up separately on the X-ray pattern. In some manufacturing processes, it is necessary to determine what effective heat treatment has been given to a sample of coke or 'amorphous' carbon. It is found that the ultimate particle size of amorphous carbon depends more upon the actual temperature of heat treatment than upon any other factor, so that the temperature to which a given sample has been treated can be ascertained with reasonable accuracy by comparison of its X-ray pattern with those of the standard period of cokes. In conclusion, the author emphasizes the fact that few recognize how wide is the scope of X-ray analysis. Certain physical properties such as the coefficient of expansion, which can be easily measured in the classical way, have also been measured by X-ray methods, and satisfactory agreement has been found. These new methods should not be regarded as merely repetitive, for new aspects of the physical property may be revealed by the new method of approach.

The Friendship of Boyle and Wren

IN a recent paper (*Bull. Hist. Med.*, 7, 970 ; 1939) Ruth Musser and John C. Krantz, jun., relate that Robert Boyle and Christopher Wren first became acquainted in London in 1648 when Boyle was aged twenty-one and Wren sixteen. In 1664, when both were at Oxford, Wren, who had been made Savilian professor of astronomy four years previously, conceived the idea of conveying medicines or poisons directly into contact with the blood of animals by inserting pipes directly into their blood vessels. The experiment was carried out on a dog in collaboration with Boyle at an Oxford meeting of the Royal Society at Wadham College, of which Wren was a member. The first experiment was made with a warm infusion of opium which was injected into one of the superficial veins of the dog's hind leg and produced profound stupor in the animal. Afterwards, experiments were made with an infusion of brown antimony oxide, which caused vomiting and was nearly fatal. Diuretics were injected at the suggestion of a famous physician who may have been Willis, and lastly transfusion of blood from one animal to another was carried out with considerable success. The experiments were brought to an end by the outbreak of plague in the summer of 1665, when Wren went to Paris, but the friendship of these two great men continued, owing to their activities connected with the Royal Society, until Boyle's death in 1691.

Meteorology in India

THE report on the administration of the Meteorological Department of the Government of India in 1938–39 covers a period during which an important stage in the re-organization of the department was completed. The scheme was planned to involve no increase in the budget grant and yet to give the following additional facilities : (1) an afternoon weather chart for the headquarters office at Poona ; (2) the re-establishment of the forecasting centre at Delhi ; (3) the establishment of a wireless station at Poona ; (4) re-organization of the superior staff; (5) the transfer of the upper air office from Agra to Delhi ; (6) an increase of staff in the R.A.F. Meteorological Offices and the setting up of additional observatories in North-West India.

The aerological observatory at Agra dates from 1914. It was originally just a research station, and the position was chosen solely with the view of getting the maximum possible information about the upper atmosphere with the aid of sounding balloons. The growth of aviation has involved the observatory in an ever-increasing number of administrative and purely utilitarian activities, and for these Agra is a backwater. It is accordingly being transferred to a new 20-acre site that has been chosen at Delhi, where it can come into closer contact with aviation interests and where it will have access to the upper wind charts prepared in the normal routine of daily forecasting.

The Imperial Council of Agricultural Research continued to finance the Agricultural Meteorology Section, although proposals were under consideration for making the section a permanent part of the department. New developments in this section included the construction of a 35 ft. tower at the Central Agricultural Meteorological Observatory, for the study of exchanges of heat and moisture between the surface layers of the soil and the atmosphere. The Calcutta office issued storm warnings during sixteen periods of disturbed weather over the Bay of Bengal. The outstanding cyclone of the year in that region was that of October 5–12, 1938, which on approaching land caused much damage and some loss of life in the Ganjam district when sea waves inundated the coastal areas and swept away houses and cattle. The Poona office had a greater number of disturbed periods to deal with over the Arabian Sea, and one cyclone redeveloped into a very severe storm early in October after having weakened during its passage across the Peninsula from the Bay of Bengal.

The Bureau of Human Heredity

THE Bureau of Human Heredity is carrying on, though with reduced activity, during the War. Although some international connexions are cut off, a compensation is the possibility of obtaining a median sample of the population through the careful examination of entrants for the Services. This is not to be lost sight of, as collaboration with medical men in examining and collating genetical conditions would be of great importance in furnishing figures of medical, anthropological and genetical value. Although the Bureau has lost several workers, it has enlisted the support of Prof. F. A. E. Crew as honorary medical secretary. Correspondence with men of science in other countries continues, but in diminished volume, which may give time for other projects, including (1) surveys of the genetic background in tuberculosis, (2) the human analogue of the transmission of cancer in animals, (3) certain immunological problems. It is hoped also to compile a preliminary list of inherited disorders and defects based on recent research for the use of practitioners and teachers. The address of the Bureau is 115 Gower Street, London, W.C.1.

Cereals for Spring Sowing

THE National Institute of Agricultural Botany has just issued a war-time leaflet (Farmer's Leaflet, No. 2, "Varieties of Cereals for Spring Sowing"). Its appearance is opportune, for it both presents an epitome of spring oats and barley in the light of their general utility, as well as their possible substitution on land which was primarily intended for wheat, but which may yet be unsown owing to unfavourable weather. There are also some varieties of wheat normally used for autumn sowing which can be sown up to the end of February with reasonable chances of success. Quality in home-grown wheat at the moment is in abeyance; but other things being equal, the same condition does not apply to oats. These are mainly intended for consumption on the farm, and the value of oat grain for all forms of stock feeding is determined by the amount of husk the grain contains. Thus, where the farmer is in a position to exercise a preference, it should be in favour of a variety with as thin a husk as possible.

In recent years nothing has happened to impair the reputations of Spratt-Archer and Plumage-Archer barleys amongst farmers and maltsters, and in general the recommendation of these varieties cannot be improved upon. There is, however, a case for the Danish varieties Kenia and Maja on rich soils, since both these barleys are early in ripening and both possess shorter and better standing straw than either of the two varieties mentioned above. On less rich soils, and where earliness in ripening is a requisite, the native varieties Standwell and Maltster may be utilized with advantage. Copies of the leaflet may be obtained from the Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Mr. A. H. Mackmurdo

THE communication entitled "The Social Organism", printed on p. 187 of this issue, has additional interest in the age and associations of the author. Mr. Mackmurdo, who is eighty-nine years of age, is believed to be the only man living who can claim to have been a friend both of Charles Darwin and of Herbert Spencer. For many years he worked with Spencer, and seventy years ago, at the age of nineteen years, he began his subscription to NATURE at the suggestion of Charles Darwin.

Announcements

CAPTAIN ROBERT KEMP has won the Buckston Browne prize for 1939 with an essay on the value of periodic medical examination in middle life.

DR. ETIENNE BURNET, director of the Pasteur Institute of Tunis, has been made a Commander of the Legion of Honour.

DR. C. G. DARWIN will deliver the thirty-first Kelvin Lecture of the Institution of Electrical Engineers on April 25, at 6 p.m. The title of Dr. Darwin's lecture will be "Thermodynamics and the Coldest Temperatures".

MESSRS. W. AND R. CHAMBERS, LTD., announce the early publication of "Chambers's Technical Dictionary". This single volume work contains terms drawn from many branches of scientific and industrial activity, and is under the editorship of C. F. Tweney and Dr. L. E. C. Hughes.

IN memory of the late Prof. V. R. Williams, the Russian authority on soils, the Timiryazev Agricultural Academy in Moscow has founded three annual prizes to be awarded for the best work on soil study and cultivation. The first prize is of 5,000 roubles, the second of 3,000 roubles and the third of 1,500 roubles. The Commissariat of Agriculture is preparing for publication a complete collection of Prof. V. R. Williams' work. New editions of the most important of them will be published this year.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 191. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

3 : 4-Benzpyrene, Paramecium and the Production of Tumours

THE blastogenic hydrocarbons are photodynamic; therefore, in order to observe their action on living cells, cultures must be kept in the dark, and examined in light not shorter than 410 $\mu\mu$. Under these conditions, using 3 : 4-benzpyrene and Paramecium, it has been shown that growth-rate is increased; this effect thus reproduces in a test-tube the increased cell-growth observed when the hydrocarbon is applied to the tissues of vertebrates, for example, the hyperplasia of the epidermal cells, when the skin of mice is painted[1].

Continuing this line of research, I have tried to reproduce the conditions under which tumours arise. This has necessitated the cultivation of Paramecium for a long time in a medium containing 3 : 4-benzpyrene; to keep the cultures going, they had to be sub-cultured two or three times a week.

Two sets of experimental cultures were maintained, containing one in a million benzpyrene, and one in five hundred thousand. In the latter, a few large organisms of abnormal shape were found on the sixty-second day. Similar abnormal organisms were also found in the one in a million cultures on the hundred and twenty-second day. This strain of Paramecium has been continuously under observation for more than two years and never have any abnormal forms been seen, either in control or experimental cultures.

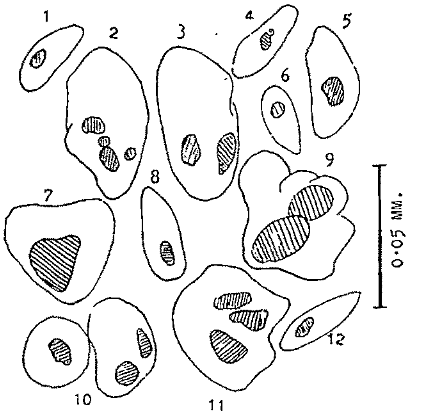


Fig. 1.

OUTLINE DRAWINGS OF SPECIMENS FIXED IN 'SUSA' AND STAINED WITH CARMALUM.

The ruled areas are macro-nuclei; Nos. 1, 4, 6, 8, 12 are normal Paramecia; No. 10 is about to divide into two.

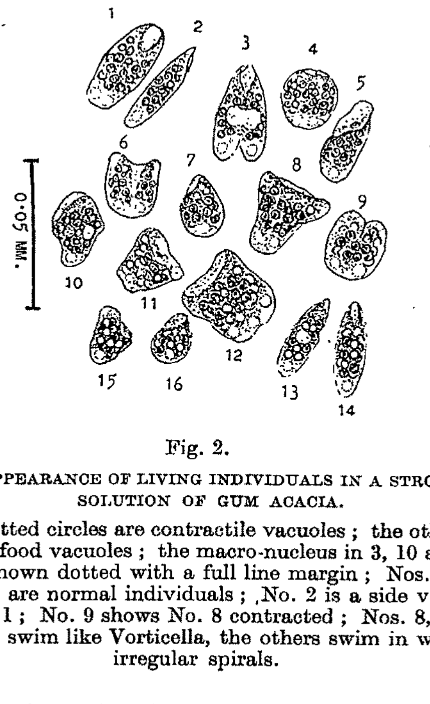

Fig. 2.

THE APPEARANCE OF LIVING INDIVIDUALS IN A STRONG SOLUTION OF GUM ACACIA.

The dotted circles are contractile vacuoles; the other circles food vacuoles; the macro-nucleus in 3, 10 and 13 is shown dotted with a full line margin; Nos. 13 and 14 are normal individuals; No. 2 is a side view of No. 1; No. 9 shows No. 8 contracted; Nos. 8, 11 and 12 swim like Vorticella, the others swim in wide irregular spirals.

The experimental cultures never underwent conjugation. Furthermore, after the abnormal specimens were removed from the cultures, the cultures continued to present only normal forms. Later, single abnormal forms again occurred in the one in five hundred thousand culture on the eighty-third day, and in the one in a million on the one hundred and sixty-fifth day.

The abnormal specimens were picked out and placed in normal media as single-cell cultures: they grew into populations of abnormal Paramecia, some many times the normal size, some midgets, some 'Siamese twins', some triplets, some no more than knobbly monsters, some presenting little departure from the normal and some apparently quite normal.

Outline drawings of some of these fixed with 'Susa' and stained with carmalum are shown in Fig. 1; examined in gum, their appearance in life is well seen and illustrated in Fig. 2.

These abnormal forms have been sub-cultured in normal medium for several months by picking out single individuals. When sub-cultured by using a platinum loop, normal forms, which are often the progeny of the abnormal, quickly outgrow the abnormal, which thus become lost.

Breeding out various abnormal forms shows how this comes about: certain of the abnormal types, especially twins and triplets (Fig. 2, Nos. 3, 10 and 12), throw normal as well as abnormal individuals. Some of the abnormal forms, however (Fig. 2, Nos. 7, 11, 15 and 16), breed true and have been kept in pure culture for many generations by sub-culturing with a platinum loop. Thus, long exposure of Paramecium to benzpyrene results in the production of a set of polymorphic cells. Here we have a striking resemblance to the assemblages of cells of which tumours are composed; it is well known that the cells from a single tumour are widely polymorphic both in size and structure: for example, their content of chromosomes may be either normal, above the normal, or below; cells with many times the normal number are common.

The similarity between the formation of a tumour by benzpyrene and the changes observed in Paramecium thus embraces the following facts:

(1) They occur among cells long stimulated to a growth-rate above the normal.

(2) They occur only after long exposure to the hydrocarbon.

(3) Only a very few of the exposed cells present the change.

(4) Once the change has occurred, it is reproduced by cell division for many generations after the hydrocarbon has been removed.

(5) The population of cells which result show wide morphological variation.

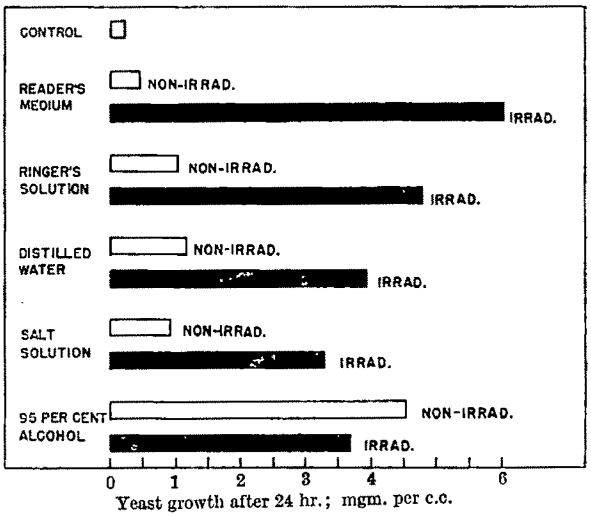
Effect of the Suspending Medium on the Production of Growth Factors by Injured Cells

In investigating the production of proliferation-promoting intercellular wound hormones by cells injured by various means[1], a study has been made of the effects of the suspending media on the production of the factors by cells injured with lethal ultra-violet radiation.

Reasoning that if the proliferation promoters are physiological products of living cells, the ratio of the production of the factors by irradiated and non-irradiated cells should be greatest when they are suspended in a favourable medium, containing nutrient material, a comparison was made of the production of the factors in distilled water, isotonic sodium chloride, Reader's medium[2], 95 per cent ethyl alcohol, and Ringer's glucose phosphate solution. Yeast was suspended in these media at a concentration of 100 gm. per litre. All suspensions were irradiated simultaneously with lethal ultra-violet until there was practically complete killing in the salt solution. The suspensions were then filtered through Berkefeld *N* filters, and the filtrates taken to dryness and made up to five times their original concentrations. These solutions were assayed on yeast according to techniques previously described[3].



The results of typical assays are shown in the accompanying illustration. The greatest production of the factors by irradiated cells and the least by non-irradiated cells occurred in the most favourable medium (Reader's). Next followed Ringer's glucose phosphate solution. In distilled water and salt solution, in which the cells had no nutrient supply, the ratio of irradiation products to controls, as well as the potency of irradiation products, were less, as would be expected if the factors were elaborated by living cells and not simply extracted from killed cells. There was somewhat greater release of proliferation-promoting factors by both non-irradiated and irradiated cells in distilled water as compared with salt solution, evidently due to the lowered osmotic pressure in the former favouring extraction. In alcohol, irradiation led to less, instead of greater, yields, the toxic effects of alcohol and irradiation together apparently killing the cells too quickly to permit as great elaboration of the factors as in alcohol alone. Were the factors dead-cell disintegration products, one would not expect any decreased yield in alcohol as a result of irradiation unless irradiation destroyed the active factor. That this could not have accounted for the lesser yields obtained was determined by separate experiments on the irradiation of active filtrates, the degree of inactivation being negligible under the conditions of the experiments.

The results indicate that disintegration of dead cells cannot account completely for the proliferation-promoting products obtained from injured cells, and support the hypothesis that injured cells release such factors into their suspending media as a physiological response to injury.

Under Coat of the Platypus

As a refugee from China where, at Chiao-Tung University and the Lester Medical Research Institute, I had been studying the structure of the wool fibre, I was offered the hospitality of the Zoological Department of the University of Melbourne by Prof. W. E. Agar, and the investigations there carried out have given rise to the matters here brought under discussion.

To disintegrate the wool fibre I had reason to steep it in a concentrated solution of caustic potash from a half to three hours. On washing in water, after this steeping, a curious phenomenon was witnessed. The wool fibre took on a beautiful regular curvature. On treating a medullated fibre in like manner, although the fibre in its natural state was perfectly straight, after treatment it took on the curvature shown in Fig. 1 with the medulla broken into short lengths. It at once occurred to me that these lengths each represented a day's growth. If this were so then there would be approximately 365 of these for a year's growth, and multiplying this number by the unit length should give the fibre length of one year's growth. This I found to be approximately correct.

One explanation of the effect here observable appears to be that the cortex of the fibre contracts while the medulla does not do so and consequently is constrained to take up the positions shown. A normal wool fibre without medulla shows a similar curvature when similarly treated, this probably being due to the different contractions of scale sheath and cortex. The periodicity of the break along the normal wool fibre is about equal to twelve diameters, that is, about one hundredth of an inch with a typical Merino wool fibre. The curvature of the wool fibre in the lock or staple is partly to be attributed to this periodicity and partly to the varying lengths of fibres composing each staple. Thus the shorter fibres decide the length of the staple and the longer fibres, of necessity, take on the curl or crimp to fit themselves to this length. On looking at the coat of the platypus in the University Museum, I was naturally struck with the 'ladder' structure shown in Fig. 2, and it was but a step further forward to ask: Is this ladder structure due to the daily periodicity—does each ladder represent a day's growth of the fibre?

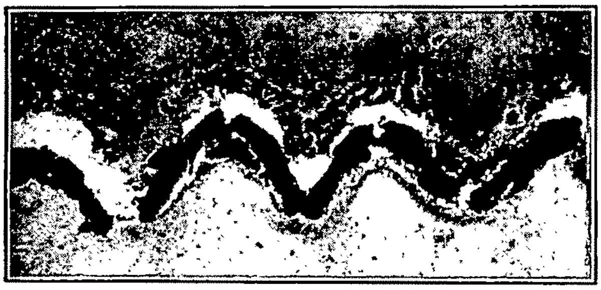

Fig. 1.

MEDULLATED FIBRE CURVED AFTER TREATMENT WITH CAUSTIC POTASH. (× *c.* 36).

Unit length approximately $\frac{3}{4}$ and $\frac{3}{4}$ of $\frac{1}{45} = \frac{1}{60}$ or 60 breaks per inch. And 365 days ÷ 60 = 6 inches, length of fibre for one year's growth.

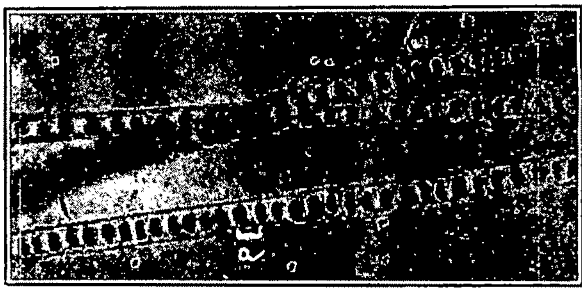

Fig. 2.

LADDER STRUCTURE OF UNDER COAT OF PLATYPUS. (× *c.* 330).

One ladder = $\frac{1}{8}$ in., and 440 × 8 = $\frac{1}{3520}$ length of each ladder. Fibre $\frac{1}{2}$ in. long, therefore $\frac{3520}{2} = 1760$ ladders or days. And $\frac{1760}{365} = 4$ years and 300 days. (Age of Animal).

By the kind collaboration of Mr. Kendall of the Melbourne Zoological Gardens and Mr. David Fleay of the MacKenzie Sanctuary, Healesville, near Melbourne, I was able to obtain fibres from two animals of known age, and on testing out the theory I was surprised and naturally delighted to find the wonderful coincidence as shown in the following table:

	A	*B*	*C*	*D*	*E*
Fibre length	$\frac{1}{2}$ in.	$\frac{1}{4}$ in.	$\frac{1}{4}$ in.	$\frac{1}{2}$ in.	$\frac{1}{3}$ in.
Length of ladder	$\frac{1}{3000}$	$\frac{1}{3000}$	$\frac{1}{3000}$	$\frac{1}{3000}$	$\frac{1}{3000}$
Ladders per fibre	1500	750	750	1500	1000
Age by ladders	$4\frac{1}{9}$	$2\frac{1}{18}$	$2\frac{1}{18}$	$4\frac{1}{9}$	3 (nearly)
Actual age	Well over $2\frac{1}{2}$	2+	2+	Not known	Not known

A is the Zoo platypus; *B* "Jack" from the Sanctuary; *C* "Gill" from the Sanctuary; *D* from the University Museum; and *E* a stuffed specimen from the Zoological Gardens.

This, however, seemed too good to be true, so I set to work to examine each coat thoroughly, and to my chagrin I found a fibre in the coat of Gill, one of the Sanctuary animals of known age, much too long to fit in with my theory. At the same time, however, I noticed the waved character of the fibres and, from my experience with wool staples and fibres which had shown a similar effect due to the variation in lengths of the fibres composing the staple, I at once thought of different rates of fibre growth which would account for this long fibre. But if my theory were correct there would only be the same number of ladders upon this longer fibre as upon the shorter fibres—in other words, the ladders would be longer. On measuring the ladders on this longer fibre I found that they were longer and that consequently on the longer fibre there would only be the same number of divisions as on the shorter, slower growth fibres. The following are the details:

For *C* ("Gill" from the Sanctuary):

Longest fibre	$\frac{1}{3}$ in.	Average fibre	$\frac{1}{4}$ in.
Length of ladder	$\frac{1}{2590}$	,, ,,	$\frac{1}{3000}$
Ladders per fibre	863	,, ,,	750
Age by ladders	$2\frac{1}{3}$	,, ,,	$2\frac{1}{18}$
Actual age	2+	,, ,,	2+

As these ladders are approximately only about one three thousandth of an inch in length, it is wellnigh impossible to count the ladders for even a two years' growth. It would seem, however, that the theory here set forth, that each ladder represents a day's growth of the fibre, is likely to be correct.

There is, however, one other matter to be considered which might invalidate the whole argument: Is the coat of the platypus composed of life-length fibres or only of year's-growth fibres? Does the platypus retain its under coat for its life or does it 'moult' or cast its coat yearly? Curious to relate, certain animals, such as the musk ox, cast their under coat yearly, but the Merino sheep, which according to the late Prof. Cossar Ewart has thrown off the outer hair coat of the wild sheep and retained only the under coat, does not cast this under coat: Merino sheep have been sheared carrying a five-years' growth of wool.

I would therefore ask the help of other workers in the elucidation of the two problems basic to the theory here advanced:

(1) Do the animals carrying a 'laddered' under coat cast this coat yearly, or do they retain the under coat for life, the life-histories of the animals being shown on the fibres just as the age and history of a tree are revealed by the rings from bark to centre?

(2) Is the 'ladder' truly representative of a day's growth of the fibre in the case of animals other than the platypus which show this ladder structure of the fibre?

The Social Organism

In the last few years science has thrown her searchlight upon social physics, making amazing discoveries. She shows that there are laws underlying social physics as immutable as those she has discovered in material physics. This fact compels the assumption that the evolution of social bodies follows the pattern of all organisms in an increasing specialization of parts with a reciprocal unification of structure. This means also that a society in its evolution becomes a social organism. The facts disclosed by science lead to no other interpretation.

In our study of natural history which now includes the history of societies, we find that all beings—mechanical, vegetal and animal—may be classed in a serial order ranging from the most simple to the most complex, and from a motor-car to a social organism. In the inevitability of this order man will find he has a sure guide to control his interference with and to direct his assistance to Nature's process of social evolution. Hence the call everywhere heard for the help of science in the work of social organization.

So long as we ranged social phenomena as a class apart from physical phenomena, science could not pass the frontiers of the latter. She had to concentrate upon improvements in mechanics and chemistry.

One cannot organize a heap of sand. Before a body can be organized there must be some binding element tending to integrate its diverse parts into a whole. This necessity becomes more evident as organisms rise in the order of their complexity. In the long past this binding element was supplied by the general concept of a superhuman power. To-day this concept is no longer general. Societies have been trying to pull themselves together either by a common defence of material possessions or by a common defence of personal rights.

But science alone can supply the missing link between the individual and society. This link is in the new conception of the social body as an organism in process of development.

The supernatural concept of the past had reference only to the individual, and in its decay it has given rise to an unrestrained individualism which has engendered disorganization and disruption instead of organization and integration.

A modern society is composed of individuals who are forced to live in association and to maintain their life by co-operation. This is the new phase and one pointing directly to the organization of the maintaining activities in accord with the law of organic life.

In the absence of scientific direction, we have been intensifying the specialization of the individual without any compensating balance in the form of a common conception such as will induce the highly specialized individuals to direct their specialized competence in building up a welfare beyond that of the individual, but one within which the welfare of each would be embodied.

In this lack of any integrating influence in the presence of elements which are in themselves disintegrating, lies the cause of the restiveness and the antagonisms of the present day in almost every European nation.

The universal instinct of man is restless in its search for law and order, and if it find no real law and order outside his own consciousness, he will create a fictitious law and order—Bolshevism, Socialism, and what not.

Here social science, which is the capital science, together with all the sciences preliminary to this, from astronomy to physiology, may keep societies out of the bog into which they are drifting. Never before has science had such an opportunity of educating and directing the civilities which constitute the civilization of mankind. By insistence upon the recognition of each body-politic as a social organism true to type, and by the habit of a conception which will enlarge the aim of science, industry and arts, this enlargement of the social functions will cause a new social structure to arise for their ample accommodation; which sociological structure will follow the pattern of physiological structures.

By the process of evolution millions of unicellular organisms have been brought into organic integration to form a multicellular physiological structure—vegetal, animal or human. By the same process Nature is incorporating millions of individuals in a multipersonal organism. This is the positive fact upon which social science is built.

Energy Changes Accompanying Magnetization

It is generally stated that the heat evolved in a hysteresis cycle is given by the expression $\int H dI$, where I is the intensity of magnetization of a ferromagnetic specimen in an effective field H, although it is very difficult to provide an adequate proof of this statement. In recent years several attempts have been made to investigate the heat liberated or absorbed when a ferromagnetic is taken through the several stages of a single hysteresis cycle step-by-step. Thus, Adelsberger[1] found that the total quantity of heat liberated by unit volume of a hard steel in a single complete cycle is equal to that calculated from $\int_{-H}^{+H} H dI$, and so provided a proof of what is known as Warburg's Law.

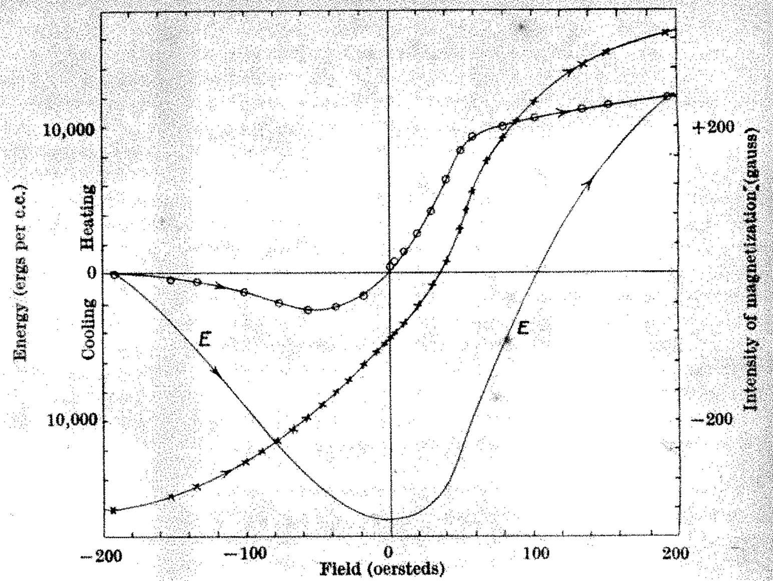

Fig. 2.

Stress 8·67 kgm./mm.².

Now, while there is little doubt about the correctness of this law, there is much uncertainty about the heat changes accompanying the magnetic changes taking place when a cycle is described in a step-by-step process. This is because the temperature changes are exceedingly small; for example, in the very favourable case of a hard steel, the total rise in temperature when its magnetism is reversed in an ordinary laboratory experiment is only about 0·005° C. Consequently, all experiments which have hitherto been made have relied either upon the use of multiple thermojunctions electrically insulated from, but in thermal contact with, a ferromagnetic rod, or upon the use of multiple specimens, each of which acted as one metal of a thermocouple, or upon the use of a divided specimen to each portion of which a thermojunction was attached, the several thermocouples being connected in series to a sensitive galvanometer. References to these experiments will be found in a recent paper by Hardy and Quimby[2].

We have recently developed in this laboratory a new and sensitive method which permits the measurement of sudden changes in temperature when some twenty thermojunctions are connected directly to an undivided rod about 5 mm. in diameter and 40 cm. long. Incidentally, the method could readily be used to measure the rate of change of the modulus of rigidity of a metal with rise in temperature. The great advantage of our method is that it enables us to measure the thermal changes accompanying magnetization processes when the rod is subjected to a steady severe longitudinal stress. In this way we have been able to obtain measurements with a hard-drawn, unannealed nickel rod, 99·67 per cent pure, the main impurity being magnesium, kindly supplied by Dr. L. B. Pfeil, of the Mond Nickel Company Research and Development Department, when under tensions of 1·70, 3·72, 5·28, 8·67, 12·1, 21·4 and 31·2 kgm. per sq. mm.

Some of the results are shown in the accompanying graphs, in which the curves drawn through the crosses are the I, H curves, the curves E represent the energy changes calculated from the I, H curves on the assumption that the expression $\int H dI$ is adequate, while the encircled points are the results of our direct measurements. Fig. 1 refers to the unstretched nickel rod, and here the agreement between the calculated and the measured results is extra-

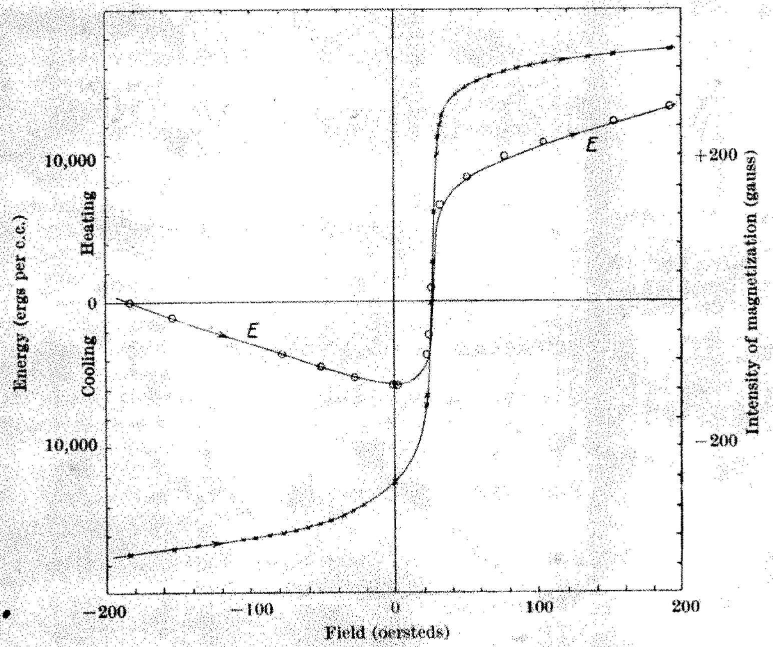

Fig. 1.

Zero stress.

ordinarily close. In our view, it is fortuitous, as we have not found such close agreement with another, slightly purer, specimen. Fig. 3 refers to the same rod under the severe stress of 31·2 kgm. per sq. mm., and is very interesting because all trace of cooling on demagnetization has vanished and no reversible changes of any kind appear. Now, Becker[3] deduces that in the case of heavily stretched nickel the entire magnetization is caused by reversible rotation of Weiss domain vectors which are forced by the severe tension to set perpendicularly to the axis of the rod in the absence of a longitudinal field. Our experiments therefore show that such processes are unaccompanied by measurable heat changes. The results of Fig. 2 are for the same rod loaded to 8·67 kgm. per sq. mm., and represent a transition stage between those of Figs. 1 and 3.

In conclusion, we wish to direct attention to the proof of Warburg's law, the lack of correspondence between the calculated heat changes and those measured directly in step-by-step alterations of *H*, and the significance of the measurements on nickel under severe tension arising from these experiments. It is hoped to publish a complete description of the method and the measurements on nickel and several nickel alloys in the near future.

Diffraction of Convergent Electron Beams

IN a recent paper[1], Kossel and Möllenstedt describe some beautiful experiments on the diffraction of convergent electron beams by transmission through thin crystals. Whereas very thin crystal flakes (or flakes of not perfectly uniform thickness ?) show the diffraction pattern of a two-dimensional lattice, the diffraction spots of mica crystals some 500–1000 A. thick show a fine structure of approximately equidistant stripes (Fig. 1) which Kossel and Möllenstedt interpret as being due to the secondary maxima of the Laue interference function

$$\frac{\sin^2\left\{\frac{2\pi}{\lambda}\cdot\frac{N}{2}c\,(\cos\theta_m-\cos\theta)\right\}}{\sin^2\left\{\frac{2\pi}{\lambda}\cdot\frac{1}{2}c\,(\cos\theta_m-\cos\theta)\right\}},$$

where *c* is the identity period normal to the crystal surface, *N* is number of cells in this direction, θ is the angle between incident beam and *c*, θ_m is the angle between diffracted beam and *c*. With $\theta_m+\theta=2\theta_0$ (interference condition of the crystal surface[1]), where θ_0 is the Bragg angle of the reflection plane—which is perpendicular to the surface—and considering the smallness of all the angles, this may be written

$$\frac{\sin^2\left\{\frac{2\pi}{\lambda}Nc\,(\theta-\theta_0)\sin\theta_0\right\}}{\sin^2\left\{\frac{2\pi}{\lambda}c\,(\theta-\theta_0)\sin\theta_0\right\}}, \quad . \quad . \quad . \quad . \quad (1)$$

which function shows minima for

$$\theta-\theta_0=\frac{md_{hkl}}{D} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where d_{hkl} is lattice plane distance, $D=Nc=$ thickness of the crystal, and *m* is any integer save 0, $\pm N$, etc.

However, this explanation based on the kinematic diffraction theory does not account fully for the details of the phenomenon: The distance between the minima $m=+1$ and $m=-1$ should be twice the distance between the minima *m* and $m+1$, whereas it is almost invariably much smaller than this expected value. Kossel and Möllenstedt, being fully aware of this fact, describe it qualitatively in terms of a dispersion with direction of the wave-length, as found in the dynamical theory of crystal diffraction. It seemed worth while to apply directly the formulæ given by this theory and, if possible, to test them.

The dynamical theory of electron diffraction by crystals has been given by Bethe[2], who, however, developed it only for the 'Bragg case' (reflection pattern); in working out the theory for the 'Laue case' (transmission diagram) along the lines followed by Ewald and others[3], a complete analogy to Ewald's *Pendellösung* is found, as might, of course, be expected. Neglecting terms of higher order, we find for the relation between the amplitude c_m of the diffracted c_0 of the incident beam :

$$\frac{|C_m|}{|C_0|}=\frac{|V_{hkl}|}{k^2}\,\frac{\sin\frac{1}{2}Dk\sqrt{(\theta-\theta_0)^2\sin^2 2\theta_0+\frac{|V_{hkl}|^2}{k^4}}}{\frac{1}{2}\sqrt{(\theta-\theta_0)^2\sin^2 2\theta_0+|V_{hkl}|^2/k^4}}, \quad (1a)$$

where $k=\frac{2\pi}{\lambda_{cr}}$, where λ_{cr} is the wave-length of the electron beam, modified by the average crystal potential; and V_{hkl} is the structure factor for the electron diffraction against the plane *hkl*.

In contrast to (1) it is seen that the argument of the sines in (1*a*) can no longer assume the value 0, its minimum value being $\frac{DV_{hkl}}{2k}$. Taking the experimental conditions of Kossel and Möllenstedt,

$D \approx 10^3$ A., $\lambda = 0 \cdot 058$ A., this will not exceed π unless V_{hkl} is greater than about 3 volts, which corresponds to a strong reflection. Minima are thus found at

$$\theta - \theta_0 = \pm\, d_{hkl} \sqrt{\frac{m^2}{D^2} - \frac{|V_{hkl}|^2}{4\pi^2 k^2}}\,, \quad . \quad . \quad (2a)$$

where $m = 1, 2, 3$ . . . etc.

With large m or small D, the second term under the root can be neglected compared to the first, thus leading to (2), Kossel and Möllenstedt's formula. It is easily seen that the dynamical correction term has the greatest relative influence on the distance between the first minima on either side of the maximum at θ_0; in the distances between minima on the same side of θ_0 the correction terms cancel to a great extent, in accordance with experiment.

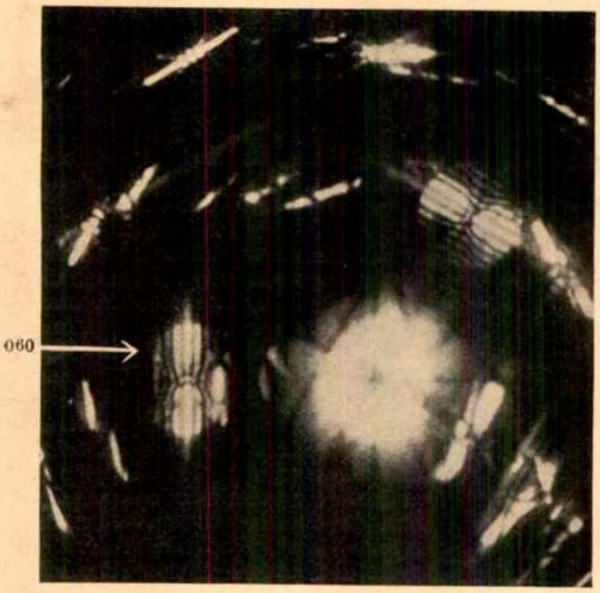

FIG. 1.

TRANSMISSION PATTERN FROM MICA WITH CONVERGENT ELECTRON BEAMS.[1]

To test (2a), V_{hkl} has been computed from the anomalous distances[4] in the diffraction spot on the left-hand side of Fig. 1, corresponding to the reflection (060). (In the figure it is seen that the position of the bands shifts when crossed by a Kikuchi line. This effect being caused by terms neglected in (2a), the distances between minima must be measured outside these regions.)

$$\frac{\theta_{+1} - \theta_{-1}}{(\theta_{m+1} - \theta_m)_{m=\infty}} = 2\sqrt{1 - \frac{|V_{060}|^2}{4\pi^2 k^2} D^2} = 1 \cdot 2,$$

where $(\theta_{m+1} - \theta_m)_{m=\infty}$ has, as a rather crude approximation, been taken from the average value of the bands $\theta_2 - \theta_1$ and $\theta_3 - \theta_2$. With $D = 900$ A. and $\lambda = 0 \cdot 058$, we find

$$V_{060} = 2 \cdot 3 \text{ volts.}$$

On the other hand, V_{hkl} was evaluated from the known atomic positions in mica, the data of Jackson and West[4] for muscovite having been used:

$$V_{060} = \frac{d^2_{060}\, e}{\pi\, a\, b\, c \sin\beta} \cdot \Sigma i\, (Z_i - F_i) e^{2\pi i . 6 Y_i / b} = 2 \cdot 1 \text{ volts,}$$

in striking agreement with the value found above.

It is thus shown to be possible to determine structure factors simply by measuring *distances* between minima in the fine structure of a diffraction spot, without any *intensity* measurement. The applicability in practice of this very remarkable way of measuring structure factors will be confined to crystal flakes of sufficiently uniform thickness; when D is not sufficiently constant, the position of the minima will shift within the region of coherence of the beam, so that the fine structure will disappear.

Selective Oxidation of Aluminium Alloys

IN a recent communication[1], S. Dobiński and M. Niesłuchowski state that "an explanation of such striking facts as the formation of a layer of pure MgO on the surface of an alloy containing barely one atom of magnesium for about 3,000 atoms of aluminium, chemical arguments are of little help. As a matter of fact, the heat of oxidation of aluminium (namely 190) is much greater than that of magnesium (143) or beryllium (131). 'Preferential' oxidation in the sense of greater chemical affinity of magnesium or beryllium for oxygen, or reduction of the previously formed Al_2O_3 by beryllium or magnesium, can thus scarcely be considered as a probable hypothesis".

The writers overlook the fact that in this case must be compared heats of oxidation which are related to the same amount of oxygen. The heats of oxidation of magnesium and beryllium mentioned above must be compared with the heat of oxidation of aluminium, also related to one atom of oxygen (namely, 126). The chemical affinity of beryllium and magnesium for oxygen is thus greater than that of aluminium, and the preferential oxidation of magnesium and beryllium is in accordance with the difference in chemical affinity of the three oxides.

The Primus Stove at High Altitudes

THE risk of carbon monoxide poisoning from Primus stoves, discussed by Prof. Yandell Henderson and Mr. J. McCullough Turner in NATURE of January 20, was realized at least eighteen years ago. The Mount Everest party of 1922 was warned about this, on Prof. Georges Dreyer's advice. He pointed out how the danger might be aggravated at high altitudes owing to oxygen scarcity, and consequently less complete combustion.

Further, the late Mr. R. P. Hope has pointed out that to melt snow quickly a little should be melted to start with, so as to get some water in the pot before filling it up with snow. This seems plausible, because air in contact with the bottom of the pot must delay heat transmission, and when a pot is filled with snow to start with, the first water to form moistens the bulk of the snow rather than settles on the bottom.

As exploration is at least as popular at high altitudes as in the Arctic, the factors affecting snow melting high up may be of equal interest:

(1) The water vapour from the flame condenses on the cold bottom of the pot. The pot must be slightly tilted, so that the water drains away to its edge. Otherwise it drips on to the burner, decreasing the efficiency, and at times extinguishing the flame.

(2) The fuel efficiency of the ordinary mountain cooker, which has a plain wind screen in place of the annular container of the Nansen type, remains constant up to 15,000 feet, at all events. With the petrol Primus it is about 60 per cent, as against 80–90 given for the Nansen cooker, the figure of 60 applying to heating of water, and not melting snow.

(3) This particular type of Primus has been used up to 17,000 feet, but Mr. Rickmers reported that it then showed signs of not being far below its ceiling.

(4) The paraffin Primus, with roarer burner, fails at about 22,000 feet, owing to cooling of the vaporizer, due to the gas having to rise above its level before it finds enough oxygen for combustion. Shortly before the War of 1914–18, Dr. Kellas tried to climb Kamet, and failed to do so largely because he was relying on this kind of Primus for melting snow.

(5) The ordinary silent burner fails at about 26,000 feet, but when modified by enlargement of the holes through which air is admitted to the flame, it continues to function in vacuum chamber up to 31,000 feet. As it approaches this level the flame becomes greatly weakened and enlarged, and clouds of blue vapour get detached, and wander upwards in search of oxygen. This modification was due to Dr. G. M. B. Dobson.

(6) The ordinary Primus pump entirely fails high up, and starts to do so comparatively low down. The safety device against excessive pressure in the container is the large clearance given to the pump barrel, combined with a spring-controlled delivery valve which only opens under a pressure of about two atmospheres. At 15,000 feet air is taken in at about half an atmosphere. It has then to be compressed to about two atmospheres above container pressure before it starts to pass the delivery valve, and the valve closes as soon as the pressure in the clearance space falls to that amount. At higher altitude the pressure may fail to attain the intensity requisite to open the valve. The solution is the substitution of a large nut, specially shaped to fill the clearance space, for the small one at the end of the pump rod.

(7) The rate of combustion with fuels not burnt under pressure rapidly decreases with altitude. Thus, comparative tests made in 1927 at 15,000 feet on Monte Rosa and at sea-level, showed that Meta took twice as long to burn in the Meta Co.'s burner at the former level. With methylated in Messrs. Falk Stadelmann's Ideal burner there was a 22 per cent increase in time. As speed is an important factor when wanting a drink, and thirst is much increased with altitude, there is an advantage in the Primus, in that the rate of fuel consumption is independent of altitude, at all events up to 15,000 feet, and presumably above.

Points from Foregoing Letters

J. C. Mottram finds that long exposure of Paramecium to the tumour-producing hydrocarbon 3 : 4-benzpyrene results in the production of a few abnormal individuals. If these are picked out and cultured in normal medium, populations of cells result, presenting wide morphological variation from apparently normal through varying degrees of abnormality to multicellular monsters. This state of abnormality was retained during reproduction through many generations. These populations resemble in many respects the assemblage of cells forming a cancerous tumour, where also wide morphological variation is found.

J. R. Loofbourow and Sister Cecilia Marie Dwyer, in continuing their investigations of the proliferation-promoting intercellular wound hormones produced by cells injured by various means, give evidence suggesting that disintegration of dead cells cannot account completely for these proliferation-promoting substances. Further support is given for the hypothesis that one response to injury of cells takes the form of release of proliferation-promoting substances into the surrounding medium.

A. F. Barker shows that the medulla of wool fibre on treatment with caustic potash breaks up into short lengths, each possibly representing a day's growth. Further work on the fibre of the under coat of the platypus shows this to have a ladder structure, each division representing about a day's growth. These observations raise further queries that need answering.

L. F. Bates and J. C. Weston describe measurements of the thermal changes accompanying the magnetization of a nickel rod in a step-by-step hysteresis cycle, when the rod is unstretched and also when it is under severe longitudinal tension. The measurements provide an excellent proof of Warburg's law, and show that 90° rotations of the Weiss domain vectors are not accompanied by measurable heat changes.

The fine structure of diffraction spots obtained from mica with convergent electron beams is explained by Carolina H. MacGillavry on the basis of the dynamical diffraction theory. From the distances between successive minima the structure factor of the reflecting lattice plane can be computed in a very simple way.

RESEARCH ITEMS

Nomad Gypsies of Hungary

BIRTH, marriage, death, are the central incidents of gypsy life in the Sárrét of Hungary, as described by Istvan Nagy of Budapest (*J. Gypsy Lore Soc.*, Ser. 3, 19, 1–2; 1940). The Sárrét, a territory of mighty morasses at the eastern end of the great Hungarian plain, which did not begin to be drained until the middle of the nineteenth century, was peculiarly adapted to their nomadic life; but social and economic circumstances forced them to settle in the villages at the beginning of the present century. Some still tend, however, to move from village to village. The Nomad or Tent gypsies were divided into tribes (now obsolete) and clans, with a head of the tribe and head of the clan, offices which have become mere titles without power. The names of the clans are derived from trades or from famous forebears, for example, the *Kolompára* clan (bell-founders) and the *Simonado* clan, so called from a famous ancestor. Some names are totemic, as the *Makara* or 'fish' family and the *Tsarneštyi* or 'fowl' family. Each clan had its specific trade and characteristics. The *Patrinara* clan are horse dealers, a distinguished, proud people of deservedly high repute. The gypsies are very prolific. Ten to twelve children in a family are quite common and sometimes there may be so many as sixteen or eighteen. Marriage is by elopement; consent of the parents is given and the marriage feast held after the return from the unofficial honeymoon. It may also be a child marriage contracted by the parents, when the two fathers enter into a binding contract kneeling before a lighted candle. The bridegroom, often not six years old, leads the bride, aged about four years, to his father's house and they grow up together. Formerly, marriage was matrilocal, the man sometimes even changing his name, but now marriage is patrilocal, owing to the influence of Hungarian laws. Divorce was easy, and no great importance was attached to virginity. The death ritual shows the double influence of the desire to be free of the dead person and his spirit, and the celebration of a joyous occasion. Hence on one side the dedication of personal possessions and gifts to the dead, on the other the wake or funeral feast at which the young people are permitted considerable sexual freedom.

Cultural Change Among Shoshoni Indians

THE importance of human ecology among hunting and gathering peoples is emphasized by Julian H. Steward in a study of changes in Shoshonian Indian culture in the western United States (*Sci. Monthly*, 49, 6; December 1939). When Frémont crossed the Rocky Mountains in 1843 he recorded that the Indians of the semi-arid deserts exemplified humanity in its lowest form and its most elementary state. These Indians were Western Shoshoni, Northern Paiute and Southern Paiute, who lived as typical food-gatherers, "dispersed in single families, without fire-arms; eating seeds and insects; digging roots". The mode of life of the Northern Shoshoni of eastern Idaho and western Wyoming, however, was in marked contrast. They were organized in large bands, hunted bison and fought their traditional enemies, the Blackfoot and Arapaho. This difference was brought about by an interaction of culture and environment which can be traced for over a thousand years. The Northern Shoshoni acquired the techniques for procuring food which made life possible in their environment, while the acquisition of the horse enabled them to exploit it to the full. Owing to the enlarged facilities in transport, food could be concentrated at a central point; and hence it was no longer necessary to live in small isolated family groups. Tribal groups were formed under chiefs or leaders, whose individual reputation might lead to the aggregation of large but not necessarily stable or long-enduring bands. Communal hunting expeditions with or without a hunting 'shaman', according to the nature of the game, were organized on a large scale and extending to considerable distances; while warlike activities for material gain or fame were practised. There was a no less fundamental change in material culture. Not only did they adopt arms and weapons suitable for warfare and hunting, but also the skin *tipi* took the place of the brush and pole shelter, and basketry for containers and utensils was replaced by rawhide, while their clothing was of dressed skins.

Bantu Lexicography

IN view of encouragement now being given to the development of a literature in certain of the Bantu languages, it is essential, the Rev. C. M. Doke has pointed out, that serious thought should be given to the provision of adequate linguistic studies including dictionaries (*Scientia*, 34, 1; 1940). After a review of existing material, the following principles of Bantu lexicography are suggested as among the essentials. (1) Alphabetical entry under the stem, without the prefix. (2) Derivative words should not have a separate entry, unless they have a special meaning not deducible from the plain function of their derivative formation. (3) Indications of the tone should be given, so far as possible, in all entries for those languages in which intonation is a significant feature. (4) Indication of the vowel-length should be given, especially in those Central Bantu languages where it is a semantic feature. (5) Phone values should be indicated where orthography is insufficient. (6) Idiomatic illustrations of the use of words should be included—of the utmost importance in any scientific dictionary. (7) Where dialectal variants are included the place of origin should be indicated. (8) Cognizance should be taken of a changing vocabulary. (9) Etymological and comparative material should be included so far as it can be afforded.

Orchis Tubercles

STUDY of the development of the tubercle of *Orchis mascula* I (B. C. Sharman, *J. Linn. Soc.*, 52; 1939) directs attention again to the peculiar capacity for growth possessed by localized parts of leaves and internodes in certain monocotyledons. In Orchis the uppermost axillary bud is carried away from the parent axis by the extension of the first two scale leaves of the axillary bud to form the sinker tube.

This extending tube includes, on the side next the parent, axial tissues of the region of bud insertion. This construction is supported by anatomy, since the vascular strands of the foliar structures enclosing the tubercle bud run up the adaxial side of the sinker tube to connect with the vascular system of the parent axis. The main storage region of the tubercle is of the nature of a root, but is peculiar in being polystelic. This peculiarity is evidently associated with food storage, since after the period of swelling the distal part becomes monostelic. The tuberization of the bud is controlled by food supplies and may also be affected by fungal infection. The droppers of tulips are very similar but usually undergo greater extension and show less evidence of food storage.

Calculation of Linkage

THE estimation of the crossing-over value is efficiently determined by the method of the product ratio (Fisher and Balmukand, 1928). To save much calculation of the ratio of the products of the cross-over classes to the products of the non-crossover classes in the F_2, W. L. Stevens (*J. Gen.*, 39, 171–180 ; 1939) has provided tables for direct interpolation, from which the crossing-over value, accurate to the fifth decimal, may be obtained, together with the variance of the crossing-over value.

Mineral Deposits of the Murchison Range

IN the eastern Transvaal a belt of basement rocks stretches from the escarpment in the west to the Kruger National Park in the east. Certain quartzites in this belt form a series of hill-ranges to which the name 'Murchison Range' is given. In a memoir of the Geological Survey of South Africa just published (No. 36, 1939, pp. 163 and coloured geological map) the mineral deposits of the belt are described by van Eeden, Kent, Brandt and Partridge. An igneous complex, hitherto unsuspected, is described as consisting of hornblende-granite and a variety of gabbroic types. The remainder of the Murchison rocks are shown to be intensely altered acid and basic lavas with an intercalated group of sediments in which occur the quartzites and quartz-schists that have determined the topography and controlled the mineralization of the belt. The whole schist belt, including the igneous complex, is invaded by the surrounding 'Old' granite, and the gold-bearing sulphide deposits of the belt are ascribed to hydrothermal processes related to the granite. The mineralization is predominantly of the arsenopyrite-pyrite-pyrrhotite type, except along a crush-zone, thirty-two miles long, known as the 'Antimony line'. Here, in addition to the normal minerals, a later suite of antimony minerals is also present. A number of minerals, of which emeralds are the most important, are associated with pegmatites. The emeralds occur in biotite-schists adjacent to pegmatites. Among the later rocks attention is directed to the exceptional abundance of dolerite dykes of Karroo age which cut the granite and schist belt and occur in two well-defined sets, one parallel to the range (N. 55° E.), the other trending N. 30° E.

Seismological Data from India

THE recently inaugurated quarterly seismological bulletin of the Government of India Meteorological Department has just been received for the quarter October–December 1938. It has been published under the direction of Dr. S. K. Banerji and consists of the interpretations of seismograms obtained at Agra, Bombay, Calcutta, Colombo, Dehra Dun, Hyderabad and Kodaikanal, all collected at Bombay, together with non-instrumental reports collected from voluntary observers by the meteorologist at Poona. The following numbers of earthquakes were registered : Agra 133, Colaba (Bombay) 103, Alipore (Calcutta) 115, Colombo 71, Dehra Dun 32, Nizamiah Observatory (Hyderabad) 72, and Kodaikanal 76. These numbers are probably not altogether indicative of the seismicity of the areas adjacent to the observatories named on account of the variation of the registering equipment. Eleven earthquakes between the intensities 4 and 6 (Rossi–Forel scale) were recorded by the observers, those of greatest intensity being one at Gauhati, two at Dibrugarh and one at Kalat.

Tsunamis

THIS is the subject of a paper by B. Gutenberg (*Bull. Seis. Soc. Amer.*, 29, No. 4, 517–526 ; October 1939) who cites eighteen publications including some due to F. Montessus de Ballore, C. Davison and A. Imamura, and exhibits some original work of his own on the Atacama earthquake of November 11, 1922, in support of his hypothesis. This is that tsunamis ('tidal waves', 'maremotos') may be produced by submarine volcanic eruptions, submarine slides started by earthquakes, submarine faulting and atmospheric conditions. At least some of the largest tsunamis have been produced by submarine slides, with earthquake waves as a trigger force. The macroseismic and microseismic data of the Atacama earthquake of November 11, 1922, indicate that the fault movement occurred inland ; the tsunamis originated from a submarine slide near a relatively feebly shaken stretch of the coast where the surface slopes steeply to a considerable depth. On gently sloping coasts, such as those of California, large tsunamis are rare and the relatively small tsunamis there are probably produced by faulting at the bottom of the ocean.

Hydrolysis of Proteins by Pepsin

LIGHT on the mechanism of hydrolysis of egg albumin by pepsin has been shed by A. Tiselius and I.-B. Eriksson-Quensel (*Biochem. J.*, 33, 1752 ; 1939) using electrophoresis, sedimentation and diffusion methods. A digestion mixture does not contain a number of products of continuously varying size and other properties but instead contains only unchanged large molecules and fully digested end products of molecular weight 1080. Pepsin is therefore assumed to attack one after the other of the protein molecules, breaking them down immediately to low molecular weight split products.

Formation of Urea

THE accepted theories accounting for the formation of urea in the organism, namely, (1) the cyclic reaction from ornithine via citrulline and arginine to urea and thus back to ornithine, and (2) urea from glutamine and ammonia, are linked up by S. J. Bach (*Biochem. J.*, 33, 1833 ; 1939) who, from results of experiments on liver by the tissue slice technique, puts forward two other possible mechanisms. These are : (3) urea synthesis from citrulline by oxidative hydrolysis ; and (4) the possible oxidative conversion of ornithine and citrulline into glutamic acid and then glutamine and finally urea by the action of ammonia.

LONG-DISTANCE BROADCASTING

DURING the earliest years of the development of radio broadcasting in Great Britain, efforts were made to restrict the area over which reception was necessary, in order to build up a service giving speech and music reproduction of the highest quality. It was with this object in mind that the regional scheme of broadcasting stations was developed. The country was divided up into sections or regions, each of which was served by two transmitters, one providing the national programme and the other a local or regional programme. In this way the majority of listeners were provided with two programmes emanating from a broadcasting station within about one hundred miles, which was considered to be the limiting range at which a reliable service could be obtained free from interference or fading.

The possibilities of long-distance broadcasting on a considerable scale were not generally admitted until about 1932; but since then, many millions of pounds have been spent by the several countries which have decided to establish wireless stations for this purpose. A review of the general development of such long-distance broadcasting was given by Sir Noel Ashbridge, Controller of Engineering of the British Broadcasting Corporation, in a Friday evening discourse at the Royal Institution on January 26.

After summarizing very briefly the main facts accompanying the development of radio communication over hundreds and thousands of miles, Sir Noel pointed out that the short wave-lengths in the region of fifty metres offer the best possibilities of covering long distances, by reason of the comparative ease with which such radio waves travel through the ionosphere. There are, however, many disadvantages and complications with short-wave transmission, which are not encountered in the use of medium waves over moderate distances. For example, in order to attain anything in the nature of a reliable service, it is practically necessary to choose a special wave-length for each transmission, depending upon the geographical location of the sending and receiving stations, the time of day and season of year and the degree of sunspot activity on the surface of the sun.

Two advantages of the use of short wave-lengths are, first, that much less power is required to cover a given distance on account of the comparative ease of transmission through the ionosphere; and secondly, it is practicable to design antenna arrays and reflectors so as to concentrate the radiated energy into a sector or zone in the desired direction. The difference in local time must be taken into account when considering the areas where reception is required, so that it is not normally necessary to transmit in all directions simultaneously.

It will thus be realized that the only really practicable means of giving a broadcasting service to any distant continent is by means of short-wave transmitters using directional aerials, so designed as to cover by zones the countries to be served. These zones can then be supplied with programmes simultaneously, by using several transmitters together, or successively for shorter periods, using one or more transmitters which can be changed over from one directional aerial system to another at suitable times. Provision must also be made for changes of wave-length to conform to the varying conditions of light and darkness, season and state of solar activity. It will be realized that in order to arrange for reception during the evening in all parts of the Empire, it is necessary to transmit almost continuously throughout the twenty-four hours.

After experimenting with a single transmitter as far back as 1927, the Daventry short-wave station was opened for service in December 1932, with two transmitters of 10–15 kilowatts in power, and five antenna systems directed towards Australia, India, South Africa, West Africa and Canada respectively. The width of beam varied with the direction of transmission, and provision was made for the necessary changes of wave-length in each case.

In order to develop the service to the greatest extent possible, systematic experimental work was conducted by the B.B.C. with the view of improving the aerial systems, and in addition the co-operation of manufacturers was obtained to develop transmitters of considerably higher power than any hitherto available for short-wave radio communication. The first improvement included the substitution of horizontal aerials for the vertical dipoles previously used, and also the arrangement of the whole antenna system with its reflector to project the radiation at a small angle above the horizontal so as to give the efficient reflection from the ionosphere in the desired direction.

At the Daventry station, as it existed before the War, about thirty separate antenna arrays were provided, supported from twelve masts 500 ft. to 150 ft. in height, the whole covering a site area of about 160 acres. Additional transmitters with outputs varying from 50 to 100 kilowatts were also installed, and facilities are available for further additions. During this expansion and development, the introduction of foreign language broadcasting changed the character of the service somewhat, in so far as it became necessary to cater for world coverage instead of British Empire coverage only.

As a result of improvements on the above lines, a broadcasting service has been established on a permanent basis, giving large numbers of people great benefit by direct listening on short-wave broadcasting receivers. In addition, however, the efficiency of the service has been increased in many colonies by the establishment of local relaying facilities, in which the signals from England are received on a high quality and somewhat elaborate central receiver, and relayed either by a separate medium wave broadcasting transmitter, or by line to subscribers connected to a central exchange.

From the engineering point of view, the main development described in Sir Noel's discourse has taken place in the astonishingly short period of five years. It has been based on many years research by some of the world's most eminent scientific workers, followed by much patient work by engineers; and it is a matter of regret that temporarily many of the short-wave broadcasting services of the world have been directed to matters of international politics rather than to entertainment and the more peaceful type of informative programme for which they were intended.

R. L. S-R.

A NOTABLE METEOR

ON March 24, 1935, a bright meteor fell through the atmosphere, in a direction apparently not far from the vertical, over the Cheviots in Northumberland, about twenty miles south of Berwick. The day was a Sunday and at the time, about 7 p.m. (G.M.T.), night was beginning to fall over England. Probably because the sky was still too light, the meteor seems to have almost escaped notice in England: one observation is reported from Scarborough, and several adults and children saw it from Oldham, falling down as a vivid shooting star with a flaming tail. From Holland, Denmark and southern Norway, however, where the twilight was almost ended, many observers saw either the meteor itself, or the bright train which it left behind it; this persisted for 20–30 minutes. Prof. C. Störmer (*Astrophysica Norvegica*, 5, 117–138; 1939), naturally with much help from others, has collected and discussed the observations, in order to determine the location of the meteor flight, and the height and other particulars concerning its train. At first, of course, the train was straight, but it gradually became very deformed; this was possibly partly on account of its sinking downwards, but mainly because of air currents, almost horizontal, but evidently varying very much in direction at different heights along the original train. The rare cases, such as this, of persistent luminous trains of large meteors, provide one of our chief sources of information concerning the velocity and direction of the wind in the atmosphere above 70 km., the other sources being the still rarer luminous night clouds, and the infrequent remains of polar auroras.

The most definite data obtained by Prof. Störmer for the meteor of March 24, 1935, were provided from a photograph of the train, already much distorted, taken at Grouw, in Friesland, at about 7.10 p.m., and three pastel sketches (in colours) of the distorted train, made at 7.0, 7.10 and 7.20 p.m.; these were made from a house in Stavanger, Norway. These sketches and the photograph were of special value because they showed an indented skyline (landscape or buildings) which enabled the azimuth of the meteor from Stavanger and Grouw to be determined afterwards (though with considerable labour). Other photographs showed the train as a spectacle, but contained no means of determining its azimuth so definitely.

The points Stavanger and Grouw together with the meteor train itself made an almost equilateral triangle of approximately 400 miles side. Yet from that distance the twisted trail as seen from Stavanger shone against the sky background with sharp outlines, and had the same colour and intensity as the moon. The light was steady, like electric light, and did not at all resemble the northern lights. It became increasingly distorted and at the same time it broadened and faded. By 7.30 p.m. (G.M.T.) it had entirely disappeared. It seemed to remain in the same spot all the time.

Prof. Störmer found that the top and bottom of the train were respectively about 60 and 50 miles above the ground, and that until about 7.30 p.m. it lay above the earth's shadow, so that it was illuminated by the sunlight; he concludes that the intense yellow colour of the train was due to this illumination.

As regards the meteor itself, it appears to have descended to a height of about 40 miles or less, and finally exploded with an intensely white light: the lowest part of its trail disappeared almost instantaneously. The meteor was said to have moved slowly like a rocket, its time of passage being about 5 seconds. As regards the colour of the train, one report gives it as fiery-red, another as red-yellow.

Prof. Störmer's discussion of this meteor and train is illustrated by plates showing the sketches and photographs.

ANCIENT WALL-PAINTING IN SOUTHERN INDIA

AN investigation has been conducted by S. Paramasivan, archæological chemist of the Government Museum, Madras, with the view of determining the technical methods employed in the wall paintings of the Kailasanatha and Vaikunthaperumal temples of Conjeevaram, the ancient Pallava capital, and in the Bagh caves of the Vindhya Hills, Gwalior State. The last named paintings, though much mutilated and stained, still constitute "a priceless treasure comparable to those at Ajanta" (*Proc. Ind. Acad. Sci.*, 10, Section A, No. 2; 1939. See also NATURE, 142, 757 and 143, 554).

KAILASANATHA AND VAIKUNṬHAPERUMAL TEMPLE PAINTINGS

The Kailasanatha paintings date from the seventh–eighth centuries A.D., and are on the inner walls of narrow cells lining the outer courtyard, depicting scenes from Hindu mythology. Those of the Vaikunṭhaperumal temple, erected by Nandivarman II (A.D. 725–790), probably date from the eighth–ninth century. They have all disappeared with the exception of a single head; but there are traces of paint everywhere.

The Pallava paintings are of the classical or Ajanta style of Hindu art. The subjects of the investigation were the carrier, the ground, the pigments and the binding medium.

Carrier. The inner walls serving as the mechanical foundation of the paintings directly supporting the ground are of sandstone, the rough surface holding the plaster fast.

Ground. Microsections showed two lines of cleavage separating three layers, (1) rough plaster, (2) fine plaster, (3) paint. Though paint and fine plaster could be separated with a sharp pin, no separation could be effected between fine and rough plaster. The respective thicknesses were: painted stucco, 2·1–4·7 mm.; rough plaster, 1·5–4·1 mm.; fine plaster, 0·3 mm.; paint, 0·3 mm.

By analysis it was determined that the fine plaster is a lime-wash, while the rough plaster is composed of lime and sand, the latter serving merely as inert material. A pure rich lime having no hydraulic properties has been used. No organic binding material, gum or glue, had been added. The strong binding of the two layers indicated that the lime-wash had been laid on while the rough plaster was still wet.

Pigments. These were yellow ochre, red ochre, terre verte, carbon, lime—the limited number being due probably to the desirability of avoiding pigments containing alkalis, and secondly, the limitations of local supply.

Binding Medium. There was no water-soluble binding medium nor drying oil, glue, albumin or casein in the paint. The technique is one of lime medium, but owing to the nature of the pigment, gum had been added to the black.

THE BAGH CAVES

Owing to the weight of the superimposed band of claystone, the walls of the sandstone caves, once completely covered with paintings, have crumbled badly. Percolating moisture has also damaged the paintings. They probably date from the early seventh century A.D. Like the Ajanta paintings they belong to the Golden Age of Indian classical art.

Carrier. The sandstone walls were left rough to hold the plaster wall; but the percolation of water has softened the plaster, while the white efflorescence on several of the paintings indicates the presence of gypsum, sodium sulphate, magnesium sulphate, etc. This efflorescence is not due to salts in the plaster, as is clearly indicated by analysis.

Ground. Three forms of plaster were used: a deep red ferruginous earth, a light red ferruginous earth, and a rough plaster of lime. Microsections here revealed three lines of cleavage in the earth stuccoes, and two in the lime, indicating four and three layers respectively. They were composed of paint, a white material serving as fine plaster, and two layers of rough plaster in the earth stucco, but one only in the lime stucco. The thicknesses were as follows. Earth stuccoes: rough plaster (1) 6·8–19·9 mm., (2) 1·0 mm.; fine plaster, 0·1 mm.; paint, 0·1 mm.; lime stucco: rough plaster, 3·4–6·5 mm.; fine plaster, 0·2 mm.; paint, 0·2 mm. The earth stuccoes are very much thicker than those of lime, while the paint film in the latter is twice as thick as that on the earth stucco and shows a certain lack of delicacy in the handling of the brush. It is probable, therefore, that the lime stucco does not belong to the palmy days of Bagh, or that the paintings on lime and earth stuccoes were the work of different groups of artists.

The fine plaster was a mixture of lime and calcium sulphate which had been applied to the surface of the rough plaster to serve as a fine plaster; but in the lime stucco the fine plaster showed no trace of calcium sulphate.

Thus the ground was prepared from naturally occurring ferruginous earth, or of artificially prepared lime plaster. The principal components of the earth plaster are silica, iron, alumina and lime, while of the lime plaster they are lime and silica. The plasters, in addition to their natural binding qualities, have been reinforced by vegetable fibres in the lime plaster in considerable quantities.

Pigments. The following pigments were identified: yellow ochre, red ochre, terre verte, lapis lazuli, carbon, lime. The colour scale is limited and evidently conditioned by local supplies.

Binding medium. No gum could be extracted by water, nor was the presence of any vehicle or organic binding medium in the paint film detected by various tests applied; but acid green indicated the presence of glue. Thus a tempera technique had been employed; but on all the paintings on plaster collected, treatment with hydrochloric acid gave a characteristic calcium reaction indicating a lime medium technique, and not a true fresco technique. The black paint gave the usual stain for glue to acid green.

THE BRITISH PHARMACOPŒIA

PROPOSED INNOVATIONS

IMPORTANT changes in the "British Pharmacopœia" are foreshadowed by reports of committees, appointed by the Pharmacopœia Commission, which have now been published by authority of the General Medical Council and are obtainable at the offices of the Council, 44 Hallam Street, London, W.1.

The most striking of the recommendations of the Advisory Committee in Pharmacy and Pharmacognosy are those which propose the inclusion in the next "Pharmacopœia", due to appear in 1941, of a large number of formulæ for medicinal preparations. These are quite distinct from the galenical products, such as tinctures, extracts and infusions of vegetable drugs, which always occupy an important part of pharmacopœias and from which medical practitioners build up their prescriptions. The object of the inclusion of these formulæ is to furnish medical practitioners with a choice of ready-made prescriptions which have been tested by laboratory and clinical experience. Prescriptions are included for compound digitalis pills, compound bismuth powder, cod liver oil emulsion, methyl salicylate liniment, calamine lotion, tannic acid jelly, acriflavine lotion and calcium gluconate injection, among some thirty proposed new monographs of the character of ready-to-use medicines.

It is understood that the Pharmacopœia Commission regards this innovation favourably, and there is no doubt that it is one which would be welcomed by the large body of general practitioners. The inclusion of these recipes in the "Pharmacopœia" would set up official standards with which the preparations would have to comply; thus a doctor prescribing, say, "Pulv. Bismuthi Co. B.P.", would have the satisfaction of knowing that the medicine supplied to his patient would be the same, wherever it was dispensed.

The Committee which was appointed to advise the Pharmacopœia Commission on the standardization of tablets has not as yet reached conclusions. Its report states that the possibility of defining tablets in the "British Pharmacopœia" has been explored and the general principles to be adopted have been worked out, but while good progress has been made towards the establishment of standards for composition, size and weight of a range of tablets in frequent use and the question of a test for disintegration has been investigated, further research is necessary before definite recommendations can be made. It is hoped, and expected, that an acceptable test for the rate of disintegration of tablets will be forthcoming before the next "Pharmacopœia" goes to press ; the need for one was clearly shown in papers read at the last meeting of the British Pharmaceutical Conference.

A curious recommendation is made to the Pharmacopœia Commission by the Committee on Pharmacy and Pharmacognosy as a test for the pungency of tincture of capsicum. It is that 3 millilitres of a solution of stated dilution "swallowed all at once produces a distinct sensation of pungency in the throats of at least two out of three individuals". Possibly the criticism will be made that this is more like a test for throats than a test for capsicum.

PETROLOGY OF EAST GREENLAND

By Dr. L. Hawkes
Bedford College, London

THIRTY years ago it might have been thought that the main forms of intrusive bodies in the North Atlantic Tertiary volcanic province were known. Then came the discovery by the Geological Survey of the cone-sheet and ring-dyke complexes, and now in a part of East Greenland very difficult of access Mr. L. R. Wager has had the good fortune to find, and, in association with Dr. W. A. Deer, the pluck and persistence to investigate, an intrusive mass which in form, composition and internal structure is unlike any hitherto known in the province. The work in the field and laboratory has been very thorough, and the results are now presented in a handsomely produced memoir which will be of absorbing interest to students of igneous rocks and doubtless a basis of lively discussion among them*.

The Skaergaard intrusive is finely exposed in a mountainous region, but as is so commonly the case with large intrusives, the original rock cover has been removed by erosion and the base is not seen. The mass narrows downwards and the 2,700 metres of its exposed thickness is interpreted as the upper part of an inverted cone some seven kilometres in diameter at its base and tilted 40° from the vertical—it belongs to the class of 'funnel intrusions'. The pre-existing rock displaced by the intrusion must have been forced upwards, and that without appreciable disturbance of the neighbouring rock. The authors suggest that the expulsion of this huge mass was a sudden act, and that the cover was shattered by expanding gases and strewn far and wide. Rather mysterious is the way in which an extensive gabbro sill, believed to have been enclosed within the cover, has become disembodied, to lie within the intrusive. Whatever the mechanism of emplacement, there came into being within the upper part of the earth's crust a volume of magma enclosed—to use Prof. Tilley's apt phrase—in a gigantic natural closed crucible, and the cooling of this perhaps unusually fluid melt proceeding under tranquil conditions has provided a remarkable demonstration of the course of differentiation in a basic magma.

Solidification first took place at the sides and top of the 'crucible' and then, more slowly, crystallization continued in the main mass within to give a series of rock layers likened to a pile of saucers, many of the layers being distinguished by a preponderance of dark minerals at their bases. This layering is so prominent that on first seeing the Skaergaard region from a ship, Mr. Wager surmised the rocks to be massively bedded sandstones. Any hypothesis of successive intrusion seems to be ruled out, and the solid mass is believed to have grown from below upwards, largely by accumulation of crystals carried down by convection currents. This postulated upward course of solidification is strongly supported by the nature of the minerals : with increasing height in the intrusive, the olivines, pyroxenes and felspars show a gradual passage from higher to lower temperature species.

The original magma, as deduced from the chilled border rocks, was of basaltic composition, and very little change in silica content is shown by the majority of the successive rocks formed, but they become unusually rich in ferrous iron, and ferro-gabbros are described composed essentially of pyroxene, plagioclase, fayalite and some quartz. Then finally and abruptly a relatively small amount of acid granophyre resulted. Notwithstanding the extreme rarity in the earth's crust of rocks of ferro-gabbro composition, the authors hold that the course of differentiation here followed is the normal one for a basic magma. But the 'crucible' was not a platinum one. Its lower part was of acid gneiss, and the magma has reacted with inclusions of granophyre. These inclusions are considered to be altered gneiss, although—somewhat strangely perhaps—the passage of gneiss to granophyre seems not to have been observed either in the wall rocks or in the inclusions. To this 'contamination' of the magma the emergence of part at least of the final acid granophyre differentiate is ascribed, and the authors subscribe to the view, now steadily gaining ground, that the normal calc–alkaline series of igneous rocks is not derived from the straightforward differentiation of a basic magma but results from the incorporation within that magma of acidic material. If this is accepted, the large granophyre intrusions of Skye and elsewhere in the province must owe their origin to the fusion of acid gneiss or crustal sialic rocks of like composition : this, however, is still a controversial matter.

SEVENTY YEARS AGO

NATURE, vol. 1, February 3, 1870

Catching Cold

PROF. SYMES THOMPSON, Gresham professor of medicine, in one of his Gresham lectures discussed the cause of the common cold. After describing the cavities concerned, he pointed out that "the ordinary cold is simply, in the first instance, congestion of the warm, moist, blood-charged membrane, which lines all these cavities and is continuous throughout the series of them. . . . This congestion is apt to pass on, under unfavourable circumstances, to inflammation, and to consequent derangement of structure. The congestion merely means that more blood is thrust upon, and retained in, the minute channels and vessels of the membrane, than those channels can healthily accommodate. The first cause of this forced engorgement is that cold is extensively applied to the internal skin, which then, under the constringing and contracting influence, drives its own blood out, partly into these surcharged tracts of mucous membrane. The injurious effect known as 'cold' is now sure to be realised if this external chill is experienced when the general system is weakened by exhaustion."

Once a cold has been "caught", Prof. Thompson says that vigorous circulation of the blood in the skin should be restored, preferably by a Turkish bath, "reinforced by the administration of stimulants, first and foremost amongst which stands concentrated food. Indeed, the Professor's pet stimulant seems to be 'Whitehead's Solid Essence of Beef'. . . . This preparation differs from Liebig's Extract of Meat chiefly in containing the gelatinous as well as the fibrinous constituents of the flesh. . . . The Gresham professor scattered the little round cakes, out of neat half-pound cases, liberally to his audience, recommending them to begin at once to fortify themselves against the inclement atmospheric influences".

Deep Mining for Coal

MR. EDWARD HULL, F.R.S., director of the Geological Survey of Ireland, read a paper before the Royal Society on the temperature of the strata taken during the sinking of the Rose Bridge Colliery, Wigan, in 1868–69. This mine was 808 yards deep, "is the deepest in the world" and the temperature at the bottom was 93½°. It may be regarded, it is said, as an experiment towards a solution of the question of very deep mining and has "an especial interest for those who concern themselves about our supplies of coal".

"IT is no secret that the present régime at the Observatory of Paris has been rather more autocratic than could be patiently endured, even in a country subjected to eighteen years of personal government. Matters have at length reached a crisis, and the Minister of Public Instruction is placed in the awkward position of having to dismiss from the public service one of the most eminent of modern astronomers, or accept the resignation of the whole of the rest of the staff of the Observatory." [The Director was M. Le Verrier.]

BEFORE a meeting of the Berlin Chemical Society, Prof. Rose reported on the first diamond to be found in Europe. A small diamond had recently been found in Bohemia, in which garnets, hyacinths and sapphires had been found for years.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PART-TIME SPEECH THERAPIST in the Psychiatric and Child Guidance Clinic—The Secretary-Superintendent, Addenbrooke's Hospital, Cambridge (February 10).

A LECTURER and a SENIOR LECTURER in the Department of Mathematics in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 88a Gower Street, W.C.1 (March 1).

ENGINEER for the Public Works Department of the Government of Trinidad—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/8993).

TEMPORARY METEOROLOGICAL ASSISTANTS (Male) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

EXAMINERS in the General Engineering and W/T and Instrument Branches of the Aeronautical Inspection Directorate—The Inspector-in-Charge, A.I.D. Training School (I.C.S./Rec.52), Brandon Steep, Bristol 1 (on Form 786).

PRESENT-DAY PROBLEMS OF YOUTH

SOME weeks ago, the National Youth Committee set up by the Board of Education announced that the Government had no intention of allowing a recurrence of the social problems of the War of 1914–18. Despite this assurance, familiar youth problems have again presented themselves and new ones have been created. A number of these were probably inevitable; others could probably have been avoided. It is not easy to resist the conclusion that, in certain important matters, the Government departments concerned with the social services have shown themselves to be regrettably lacking in foresight.

Nor is it easy to resist the further conclusion that some of them are exhibiting very little alacrity, method or determination in dealing with problems which appear to many to be urgent. Doubt on this point may be permissible, for it is probable that their hands are being tied by the Treasury, through reduction in financial assistance. But it might not have arisen at all, if these departments had shown more frankness in their pronouncements. Nothing is more likely to stiffen the task of the Director of Home Publicity at the Ministry of Information—that of making public opinion receptive to political decisions—than an accumulation of unanswered or half-answered queries on such matters.

If bewilderment is produced in this way, further psychological difficulties are created. In some cases, formidable resentment is built up; in others, apathy becomes all-pervasive. During recent weeks, both these reactions have been exhibited plainly; and nowhere more clearly than among those concerned directly and indirectly with problems of juvenile employment. In their treatment of a number of these problems, some departments seem lately to have displayed neither frankness nor wisdom.

Why, for example, has the Home Office had to undertake to consider applications for exemption from those sections of the Factories Act of 1937 which regulate the hours of work of juveniles? Surely the evidence collected during the War of 1914–18 by the Health of Munition Workers' Committee suggested strongly that even the regulations of the Act of 1937 were not entirely adequate? It is not to be doubted that the factory inspectors of the Home Office will use their new powers with great discretion, but it is more than likely that some of them will feel compelled at times to declare decisions which they will reach with considerable reluctance. From various parts of the country it is already reported that two of the most evil consequences of unsuitable working hours—listlessness and loss of 'further education'—have once more manifested themselves. In his recent King George Jubilee Trust report, "The Needs of Youth", Dr. A. E. Morgan remarked, "British industry will not be ruined by being deprived of the privilege to exploit half-educated boys and girls". This pungent comment is as true in war-time as it is in times of peace. Even in factories which retain their pre-war time-tables, the *tempo* of production is apparently increased sometimes to such a pitch that the physical and psychological state of the slower workers is seriously affected.

Has the Home Office decided, in the face of all the evidence available on this subject, to surrender to the Ministry of Supply? If the outlook indicated by this ruling is maintained, what will be the quality of Britain's democracy at the end of the present conflict? For some workers, possibly even for the younger ones, patriotism may provide an additional incentive; but, as Dr. H. M. Vernon reminded his hearers at a meeting reported in NATURE of February 3, p. 174, "Nature cannot be defied indefinitely."

Again, why has the Ministry of Labour permitted the suspension of certain of the vocational guidance and after-care activities of its Juvenile Advisory Committees? Why has the Ministry's scheme for the transference of young workers apparently ceased to function, while the need for it continues? And why have some at least of its hostels for these boys and girls closed their doors? Even when allowance is made for difficulties created by evacuation, such actions are bound to perplex those who had been led to believe that the Ministry took a broad view of its responsibilities towards young people. It is perhaps significant that its war-time opinions on vocational guidance and after-care have not been accepted without question by other experts. Its advice has been ignored by many local education authorities who have juvenile employment officers of their own and in whose districts the Ministry is only in indirect command. The very fact that acute disagreement exists here suggests that the Ministry's case for curtailing its activities is by no means unarguable. The 'rebels' are unquestionably right in maintaining that, both from the point of view of the individual, who needs a congenial occupation if he is to exert himself fully, and from the point of view of the nation, which urgently requires efficient workers, sound vocational guidance is at least as necessary now as it was before the War. If the Ministry feels unable to continue this branch of its work, it might well ask local authorities whether they will take it over. The machinery for such a transfer already exists.

Furthermore, why have the Civil Service Commissioners had to suspend their normal examinations for entry to this Service? A very considerable number of able boys and girls—and their parents and teachers—have lately been profoundly disturbed by the Commissioners' unexplained move. In all parts of the country, secondary school principals, who are in a good position to judge the public reaction to it, are voicing strong criticisms of the Government's attitude to this problem. It is understood that alternative proposals, put forward by the staff side of the National Whitley Council, are being considered. Consideration of them should be completed speedily and positively. Purely negative decrees on employment matters by the Government can scarcely be held to provide good examples for private employers; nor can they easily produce the occupational incentives which are so much needed by young people at the present time.

Indeed, the negative character of the official attitude to many employment matters is extremely disconcerting. No reasonable person would expect the Government to show unerring foresight in making plans for dealing with situations which might never arise. But there is, unfortunately, much evidence which suggests a marked lack of constructive and co-ordinated thought. A striking example is to be found in the astonishing absence—an almost total absence—of official comment on what has been called the "16 to 20" problem.

Lord Derby has suggested that voluntary labour camps should be provided for boys of secondary education who fall within this age-range. His proposal has been discussed at length in the correspondence columns of *The Times*. It is doubtful whether the space devoted to it has been commensurate with the usefulness of the suggestions put forward, or, indeed, with their relevance; for most of them—not unnaturally, perhaps—have been concerned primarily with the comparatively limited problem of the boy whose parents have been able to send him to a public school. The Ministry of Labour's contribution to the discussion—communicated through *The Times* Labour Correspondent—has been a statement of the conditions under which boys in this age-group may be admitted to its ordinary technical training centres. Is it surprising that the head master of a large south of England secondary school reports that his boys are "simply bewildered" about their futures?

Could not the Ministry of Labour at least stress frankly the need for considering the post-War effects of such schemes as those proposed by Lord Derby and his supporters? They certainly need consideration; for many of the suggestions seem to have been based on false assumptions. One is that many boys in the 16–20 group have sufficient money and influence to enable them to make an entirely fresh occupational start after the War and therefore need not worry if, in the period prior to their military service, they are called on to do something which bears little relation either to their abilities or to their interests. Another is that, when the War is over, the national recovery will not be hindered by the presence in the community of large numbers of middle-class young men devoid of occupational training and experience suitable to their talents and temperaments. The vast majority of those leaving secondary schools cannot afford, even in war-time, to be ushered silently into unsuitable 'stop-gap' occupations; nor can the nation afford it. It is clearly important that these youths should be regarded, not as unfortunate liabilities to be put temporarily into places where they will create a minimum of trouble, but as citizens-in-training. The head master of Winchester College, who is chairman of the Head Masters' Conference, has very properly insisted that, in any work scheme produced for the 16–20's, the opportunities offered should be *real.*

Is it too late to suggest that this problem should be tackled experimentally by the Ministry and the Board of Education? Individual head masters here and there are doing this in their own way, and according to their own ideas: for example, by providing special commercial courses for senior boys who would normally have entered clerical occupations this year but have been unable to do so, and by increasing the amount of time devoted to O.T.C. activities. The Board of Education has already dealt with one of its own difficulties by allowing non-graduate students to enter its teachers' training colleges at the age of seventeen. The Y.M.C.A. has proposed the formation of a Boys' Land Army. A number of professional training organizations have begun to provide shortened courses of instruction. One well-known rubber company has announced its intention of awarding a certain number of 'scholarships', providing free training and maintenance grants, to boys between the ages of 17½ and 19. Could not these experiments be co-ordinated and extended? If this were done, a great deal of the resentment and apathy noticeable at present might rapidly be dissipated and much valuable data might be gathered. But it will have little worth if it be not done seriously and with a determination to act on the results obtained. The adoption of an experimental approach, which might well make use of psychological techniques of vocational guidance and selection, must not be made an excuse for shelving decisions by bestowing semi-official blessing and inadequate funds on ardent advocates of reform, in the hope that the problem will quickly lose its urgency by the absorption of young men into the Fighting Services. An appropriate first step would be the appointment, by the departments concerned, of a director of research.

SCIENCE FOR A NEW AUDIENCE

Science and Everyday Life
By Prof. J. B. S. Haldane. Pp. 284. (London: Lawrence and Wishart, Ltd., 1939.) 5*s.* net.

THOSE who subscribe to the *Daily Worker* are privileged to read every week some of the most successful expositions of popular science in contemporary journalism. It is not possible to discuss the implications of this fact in a brief review; but if Prof. Haldane's modesty would permit him to admit that he is both a first-class man of science and a first-class educator, his faith would make him insist that he would be neither were he not a first-class Marxist. This collection of articles is certainly as political as it is scientific, and its author would believe it less scientific if it were less political.

The book should be read not only by the general public but also by all those who aspire to make science intelligible to the general public. To these the author's technique will be a liberal—as well as a Marxist—education. Why is it so successful? Apart from the blustering, ozone-laden style through which Haldane introduces himself to his readers, rather as the *homme moyen sensuel* than as the ascetic scientist, there is the picture which he seems to carry in his eye of what his reader is like. He does not write for readers in their capacity of consumers willing to fill a leisure hour with science gossip, but rather as producers into whose labours science has already entered at every point. He creates a synthesis between the theories of scientists and the actions of workers, miners, chemical manufacturers, barmen, who are applied scientists by virtue of economic necessity. He does not describe disease as an abstraction but shows it always to be occupational, a function of the social environment.

Above all, the politician in him prevents Prof. Haldane from committing the commonest error of men of science trying to write for the man in the street, namely that emotion, or personal equation, is as deadly then as in the writing of a monograph for the *Philosophical Transactions*. He believes that the voice of honest indignation is the voice of science and so he writes.

Occasionally Prof. Haldane permits himself the luxury of statements that, taken at face value, could no doubt be challenged. For example, he says that "By postponing marriages, the Means Test not only causes unhappiness, but actual mental defect". It is improbable that Prof. Haldane could produce evidence that the means test has actually increased mongoloid imbecility, but then he would point out that the only sort of person likely to take him up on such a point would be "Reactionary biologists" some of whom think "that the unemployed should be sterilized".

Two passages especially suggest how far we have gone since the day when popular science catered chiefly for ladies who sought a change from fancy sewing. The first is where Prof. Haldane sums up against astrologers in Sunday papers: There is no righteous indignation; astrology is not an insult to that abstraction, scientific truth; "Astrologers and palmists are very useful to the cause of capitalism. They help to persuade people that their destinies are outside their control. . . . If enough people learn how the joint fate of us all can be altered, things begin to happen which mean the end of capitalism as well as of astrology and palmistry".

The other passage gives a significant criterion for judging between cause and cause. "We are quite right," Prof. Haldane points out, "to emphasize the environmental factors in tuberculosis just because we can control them. We say that a house caught fire because someone threw down a cigarette end, and not because there is 21 per cent of oxygen in the air". Implicit here is the doctrine that the duty of the scientist is not to explain the world but to alter the world, and implicit on every page of the book is the author's belief that his duty as an educator is not to help his readers simply to understand phenomena but to become the *primum mobile* of their evolution.

JOHN LANGDON-DAVIES.

CHEMISTRY OF ORGANIC COMPOUNDS

(1) Ausführliches Lehrbuch der organischen Chemie

Von Wilh. Schlenk. Band 2. Pp. xvii + 896. (Wien und Leipzig: Franz Deuticke, 1939.) 30 gold marks.

(2) The Chemistry of Organic Compounds

A Year's Course in Organic Chemistry. By Prof. James Bryant Conant. Revised with the assistance of Dr. Max Tishler. Pp. x + 658. (New York: The Macmillan Company, 1939.) 18*s*. net.

(3) Introduction to Practical Organic Chemistry

By Dr. Frederick George Mann and Dr. Bernard Charles Saunders. Pp. ix + 191. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1939.) 4*s*. 6*d*.

THE three books under review are so closely related to modern organic chemistry that they are conveniently taken together. They represent in a very marked manner the kind of organic chemistry which the young man of the present day, and perhaps for the next twenty-five years, will have to learn if he desires either to make the subject his life-study or intends to use it merely as a stepping stone to other walks of life.

(1) The reputation of Prof. Wilh. Schlenk as a writer and teacher was established when Vol. 1 of the text-book was published. The appearance of Vol. 2 enhances that reputation. To an earlier generation the two volumes must show a striking resemblance to that wonderful treatise started by Victor Meyer and Jacobson, the first volume of which appeared before Victor Meyer's death but which was finished later by Jacobson and others. It was the first volume that contained both knowledge and wisdom and showed that even a book on organic chemistry could be made readable and interesting to the lay mind. The book contained such a wealth of knowledge expressed in such beautiful phrasing that it is doubtful whether we shall ever see its like again.

Vol. 2 of Schlenk's book, in general treatment and in power of expression, follows, with Vol. 1, as commendable modern equivalents of the first volume of Meyer and Jacobson. Like Victor Meyer's book, it is no mere record of an endless number of compounds, but deals only with such substances or group of substances as lead to or enforce the establishment of some theoretical point of value in the discussion of some principle underlying the science. The discussions on these points are by a master mind and make excellent reading. They give the book an interest unusual in a scientific text-book. According to the short preface the author intends to publish a Vol. 3 to complete the issue. If the third volume is as good as the other two, the whole work will form a striking addition to our chemical literature. There is, of course, the difficulty of language for the English reader, a difficulty which is not overcome by a translation, if such were possible nowadays. The true charm of the book lies in the expression in the German language of the enthusiasm of a man who loves his subject and is prepared to give all he possesses in unstinted measure to those who can appreciate the gift. An English translation would be but a dead-sea apple and turn to dust and ashes in the mouth. It would be lifeless. Despite present circumstances, we must place a mastery of the German language in the forefront of our educational schedule. The Germans as scientific people rank high and we should be curiously handicapped if we failed to understand or to appreciate any new discovery they might make, the lack of a knowledge of which might stand us in ill-stead.

The free interchange of knowledge as it was say forty years ago, no longer exists. Many things have caused the change, notably the supposed need for commercial secrecy. It is true that many firms permit publication by their employees, provided all requirements of the patent laws have previously been met. This involves, usually, some little delay, but can scarcely be regarded as a hardship. Other firms, unfortunately, do not grant such privileges, and much useful and perhaps essential knowledge is buried in their archives. Team work in industry has come to stay because it is by far the best means of attacking a general problem, and although the team worker is individually the loser by sharing any new discovery with others, it is made up to him in other ways and the new discoveries can be published by the firm under the names of the team-workers concerned. For it is essential that new knowledge should be published, annotated and recorded, otherwise progress will be impossible. One can scarcely realize what the present position of knowledge would be had the research workers of the past evaded the path of free publication. Nevertheless, with good will and co-operation between industrialist and scientist, the terms being used merely to denote two different types of scientist, all will be possible and the goal reached by which all new knowledge will be annotated and pigeonholed for the benefit of succeeding generations.

Let us, for example, be certain that a book like Schlenk's is full and unrestricted and that nothing is held back either by reasons of commercial exigencies or for any cause whatever. It is surely in the interests of industry itself that there should be unrestricted publication of all new knowledge, for it is unthinkable that new knowledge can be discovered if any industry buries the information it has gained on account of some real or supposed desire to prevent a competitor from taking advantage of it. By burying its knowledge, a firm reaps no real benefit but injures itself by checking the advance of knowledge in other branches of the subject with which it deals. The research worker is thereby prevented from knowing what has been discovered, the progress of discovery is inhibited and the direction on which all true progress depends is lacking.

(2) President Conant is a great administrator, and his power as an author has been shown in many ways, notably by his publication of organic syntheses and by the first edition of the book under review. The revised edition is published after six years with the assistance of Dr. Max Tishler, research chemist at Mercks. The new matter deals mainly with the advances made in that region which lies between abstract organic chemistry and biology, because it is undoubtedly along the lines of organo-physiology and organo-pathology that discoveries of vital importance to mankind will be made.

It is doubtful whether we shall succeed in discovering the true chemistry of life, but we shall get sufficiently near to that discovery to enable us to prepare biological substances the lack of which in the human system leads to disease and death. It is perhaps impossible to renew the worn-out human machinery but by the application of essential organic compounds, which the ageing system fails to produce, it will be possible to prolong life far beyond the three score years and ten of the Psalmist. Whether this is desirable or not is an open question, for youth is not likely to view with equanimity the picture of seniors active and virile at the age, say, of one hundred and twenty. Values must, however, adjust themselves in this ever-changing world, and if men can retain all their faculties at one hundred and twenty years of age, they are not likely to consider the objections of youth in the matter.

In Conant's book, although it bears the subtitle—"A Year's Course in Organic Chemistry" and is therefore written for those other than the men who intend to make organic chemistry a life-study, much of the higher biology is given in full detail. It is clear that the authors understand the great truth which all those who appreciate the science must recognize, namely, that it is only by the combination of organic chemistry and biology that progress can be made. Ultimately, the empiricism of biology will disappear and the new science of biochemistry will be based on organic structure and principles. When this happens, the clouds will pass away and in the brilliant light of the unfettered sun, discoveries will be made of far-reaching importance to the human race.

(3) This practical organic chemistry is doubtless a useful book for laboratories in which the course of laboratory work followed is in accordance with the text. For it happens that text-books of

this kind are usually written for the course chiefly to assist the teacher; it is rarely that the course is dependent on the text-book, although in some instances this may be the case. The present book is probably written of the Cambridge laboratory course and shows incidentally that teaching in these laboratories is based on right principles. The book, no doubt, will serve for any of the organic courses in our universities and university colleges, but there it will have to compete with a host of similar books, some written for the requirements of a course, which are practically unassailable, having become firmly established by usage, others of general application which again have been established by long usage and are also practically unassailable from outside.

Nevertheless, the book under review is a good one and deserves fully all the success it can obtain. It is difficult to say, however, that it has any outstanding features which render it a book apart from its many competitors.

JOCELYN THORPE.

ENZYMES

Die Fermente und ihre Wirkungen
Von Prof. Dr. Carl Oppenheimer. Supplement. Band 1 (zu Band 1, Specieller Teil: Haupt-Teil 7–12.) Pp. xii+782. Band 2 (zu Band 2, Specieller Teil: Haupt-Teil 13–22). Pp. x+783–1738. (Den Haag: Dr. W. Junk, 1936, 1939. 2 vols., £12 10s. Bibliography (1924–1938). Pp. 1–128.

FORTY years ago probably relatively few chemists or physiologists had any knowledge of enzymes, which were considered to be somewhat mystic bodies; the biochemist, if he existed, was regarded as a hybrid. Emil Fischer had put aside the sugars for the time and commenced his work of taking the proteins to pieces.

To-day it requires a book of 1,738 pages in order to give concise information about the enzymes, and this is a supplement to an equally large volume, and consists mainly of new matter and not a repetition of the old. The preface to the supplement is dated August 1936 so that it has been three years in preparation, obviously three years of hard labour for the compiler.

The constitution of the enzymes is largely unknown; they cannot be listed and formulated in the graphic chemical shorthand which has so facilitated the progress of chemistry and enables the expert to achieve so much with the vast majority of natural and synthetic substances. This makes it doubly difficult to deal with the enzymes in books: they have to be classified by what they do, by the reactions for which they act as catalysts, rather than by what they are.

The difficulty has been largely overcome by Oppenheimer by an elaborate division into classes and frequent subdivision into entities resembling a zoological catalogue, and ultimately into numbered paragraphs. In consequence, with the aid of the schedule of contents it is as easy to look up a particular enzyme as it is to look up a compound of known structure in an organic chemical dictionary.

The task has been accomplished and the book contains the latest up-to-date information about each and every enzyme, in the space of a few pages in paragraphs, subject only to the time lag of publication. It has been issued in parts, at irregular intervals during the three years, of which ample reviews have been given in these columns with the object of keeping workers on particular enzymes in touch with the progress of the supplement.

The extent of the interest in enzymes is evidenced by the amount of published work on them. The research has gone on side by side with that on vitamins and hormones, and some connexion or relation between these and the enzymes is beginning to appear. Their significance as catalysts of vital reactions has long been realized, but the stage has now been reached of understanding the mechanism of such reactions and the manner in which enzymes take part in them. Vitamins and hormones have become therapeutic agents, they are injected or taken by the mouth so that a deficiency in the body of such 'reaction-promoting' materials can be corrected. This is scarcely true as yet of the enzymes though they are sometimes administered; more probably, the giving of hormones liberates enzymes which were previously dormant and brings them into action.

Apparently; vital reactions take place in a chain though, as this term has been appropriated by the physical chemists to connote another type of reaction, it is necessary to substitute the term 'series of substances'. Each compound in the series does something to or with another; the presence of each is necessary for the completed reaction. Some of the compounds are ordinary normal products of the cell, some are present only in minimal quantity, others are in the resting state as part of larger complexes and have to be unlocked, so to speak, before they react. A satisfactory book of reference contains the facts or indications of such, from which the worker can build up further experiments and check his own theories.

From time to time there arise individuals, diligent and of orderly mind, gifted at cataloguing and summarizing the literature. Beilstein has done this for organic, Mellor for inorganic, Abderhalden for physiological chemistry, Oppenheimer for enzymology. The completion of this work entitles him to be ranked with these others as a benefactor to experimental science.

All of them have made it easier for workers to-day to press forward their experimental investigations by which alone, slowly but surely, the truth is unveiled.

E. F. ARMSTRONG.

BIOLOGY FOR SCHOOLS

(1) A School Course of Biology

With Suggestions for Practical and Field Work. By L. J. F. Brimble. Pp. x+470. (London: Macmillan and Co., Ltd., 1939.) 6*s*.

(2) Biology for Junior Forms

With Instructions for Simple Practical Experiments. By M. R. Lambert. Pp. 320. (London: Macmillan and Co., Ltd., 1939.) 3*s*.

(1) IN the preface to his book, Mr. Brimble writes that "the teaching of biology is still in the experimental stage, and thus the completely satisfying course which covers the period allocated to it in secondary schools is still to be formulated". It is inherent in the nature of progress that this completely satisfying course may never be attained, but it stands to the author's credit that here, as in his "Intermediate Botany", he has made a valuable contribution to biology teaching. "A School Course of Biology" bravely attempts to deal with biology as a whole science in which no use is made of the "convenient" divisions into botany, zoology and physiology. The other general feature of importance is that the elements of human biology are liberally distributed throughout the text, and here lies the reason for much of the intrinsic value and attractiveness of the book.

Although the requirements of candidates for school certificate and matriculation examinations are more than adequately provided for, whenever possible the author has carefully diverted the issue to deal with matters that make up the natural and ever-present interests of pupils. Great prominence is given to economic uses of plants and animals, and attention is focused upon the human being in a section on human anatomy and physiology, with the attendant medicine, hygiene, health and fitness. Historical references are repeatedly inserted to illumine the facts presented. The pupil is invited to consider familiar plants and animals before attempting the unfamiliar. Another feature of considerable value is represented by the author's attempt to inculcate the spirit of inquiry by the frequent inclusion of suggestions to the effect that though much is known in science, the vast ocean of discovery lies largely uncharted.

Each chapter contains suggestions for practical work and, as an aid to examination candidates, some two hundred typical questions are provided. The 355 diagrams and photographs have been collected from many sources and are varied in appearance. The great majority of the diagrams have been prepared by the author himself; these are uniformly excellent. It is to be desired that, when the book reaches its second edition, the author should even further extend its attractiveness by replacing the few poorer diagrams by yet more of his own. There are a few inaccuracies which are of a trifling nature. The only outstanding omission is that no reference is made to the pasteurization of milk, and the section dealing with soil might have been extended.

Mr. Brimble's book should soon find its way to all schools where biology is taught and should be a real boon at present to teachers whose schools have been evacuated.

(2) "Biology for Junior Forms" is the adapted third book of a series that was written for senior schools. This series was written using a concentric system so that each of them would cover a year's course. The third book has accordingly been published for use in the junior forms of Secondary Schools. It is doubtful, however, if it will achieve the same success in its present form as in the original. The pace of the introductory chapters appears to be too rapid for younger pupils, strange terms frequently being introduced without adequate explanation. The references to the earlier books of the series might also be disturbing to pupils having no previous acquaintance with them, while the exclusive divisions into botany, zoology and human physiology could scarcely be permitted in a book that is meant to be the foundation for Mr. Brimble's book on biology.

This little volume contains much useful material, however, and with a different presentation would perform valuable service in the lower forms of secondary schools.

T. H. HAWKINS.

CIRCULATION OF THE BLOOD

The Control of the Circulation of the Blood
By Prof. R. J. S. McDowall, with the assistance of Lt.-Col. G. E. Malcomson and I. McWhan. Pp. xv+619. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 73*s*. 6*d*. net.

PROF. McDOWALL is to be congratulated on the production of a comprehensive 'Handbook' on the control of the circulation of the blood, with seven thousand references to other works. It is surprising that he has found time to write it without interrupting either his teaching or his research work. His book covers the ground as completely as such books can, and does not follow the easy course of disposing of early work by reference to previous reviews, but contains much discussion of work published before 1900, where such work is still considered important.

A few minor errors are inevitable, and a warning to this effect is contained in the preface. They can do little harm, since no serious man of science would rely on a monograph without referring to the original literature. The 38 figures are all taken from the author's own experiments, and their even distribution through the book reflects his close practical knowledge of all the problems discussed.

There are 150 pages dealing with the control of the blood vessels in various parts of the body, 100 pages on the heart, 80 pages on adrenaline, and chapters on the effects of carbon dioxide, anoxæmia, temperature, sleep, exercise, posture, hæmorrhage, the pituitary, the hypothalamus, and vasodilator substances. The action of ions and the chemical transmission of nervous impulses are deliberately and wisely omitted; but it is a pity that there is no adequate account of the various theories that have been propounded to account for vascular shock. Perhaps the explanation is that the book has been confined to physiological phenomena, and shock is excluded as pathological.

All physiologists who work on the circulation will covet this book, which will give them a long list of references, and a considered summary of many problems. It will save some of them from arduous searches in libraries and others from the publication of facts already known.

J. H. GADDUM.

STUDIES IN TELEPATHY

Experiments in Telepathy
By René Warcollier. Edited and abridged by Gardner Murphy from "La Télépathie", articles in the *Revue Métapsychique*, and recent Unpublished Studies. Translated by Josephine B. Gridley. Pp. viii + 250. (London: George Allen and Unwin, Ltd., 1939.) 7*s*. 6*d*. net.

THIS book is a collection of material taken from various publications by M. René Warcollier and put together with a foreword by Prof. Gardner Murphy of the Department of Psychology of Columbia University.

For some thirty years, M. Warcollier has been studying the phenomena ascribed to telepathy, and in this volume he sums up his impressions of what he has learnt and gives numerous examples of successes in the reproduction of drawings, diagrams, etc., many of which are clearly not due to chance alone.

The main object of this collection of papers is not so much to offer fresh evidence for the existence of a telepathic faculty as to study and discuss the mental processes involved, and to try to ascertain how to produce the phenomena at will and thereby to initiate a detailed examination of the laws underlying them. Although the author was not successful in discovering any basic laws, his notes provide suggestive material for future experimenters. Thus some of his results indicate that ideas repressed by the agent seem to be transmitted better than those upon which his attention has been concentrated; whilst the factor of the agent's own activity as compared with that of the percipient is seen in a number of experiments. On the other hand an increase in the number of agents seems to lessen their influence, whereas the opposite is true as regards the percipients, who, in certain cases, appear to be in mental rapport with one another.

Although much of M. Warcollier's work does not seem to be open to the kind of statistical treatment which is now being applied to problems of this kind, and through which we may hope to gain a greater insight into the questions involved, his work is of considerable interest, since he is particularly concerned with the kind of mental factors at work if the phenomenon is a real effect and not due to unascertained normal causes.

THE PUBLIC RELATIONS OF SCIENCE*

BY DR. WESLEY C. MITCHELL,
PROFESSOR OF ECONOMICS, COLUMBIA UNIVERSITY

UNTIL recently the attitude of the public toward science seemed to be growing more appreciative. There have always been folk who objected strenuously to the supposed implications of certain scientific hypotheses, but on the whole science was generally esteemed the most progressive factor in culture, man's best hope for bettering his lot upon earth. Of late this tide of approval has ebbed. There is a widespread disposition to hold science responsible for the ills men are bringing upon themselves—for technological employment, for the rise of autocracies, for the suppression of freedom, for the heightened horrors of war. For their part, scientific men are appalled at the hideous uses to which their discoveries are put. They feel an urge to combat the misuses of science, to protect the social values they cherish, but what they can do is not clear. The quandary is one that all who cherish science should face, however unwelcome and difficult the task.

I

Let me start by recalling certain changes in the relations of science to society that may help us see our present problems in historical perspective.

The beginnings of scientific knowledge have been traced to man's dealings with the implements of his daily life—the sticks and stones, the skins, fibres, and clay he shaped to his uses, and in the shaping learned to know. At a later stage of cultural advance, thinking about natural phenomena, like thinking about religious observances, tended to break away from direct associations with daily work. Such efforts to understand the world as the Middle Ages made were concerned chiefly with problems of a divine dispensation. Observation was not pertinent, and factual tests of conclusions were not possible.

The re-birth of science in the sixteenth and seventeenth centuries was accomplished by turning from the study of concepts back to the study of Nature. The new orientation was characterized by close observation, by the invention of devices to make observation more penetrating and accurate, by purposeful experimentation to simplify the processes observed, by close attention to quantity as well as to quality, by the practical application of mathematics to express the relations observed, by reformulation of concepts to fit the findings, by critical checking of one investigator's work by others, by the cumulation of tested conclusions in old fields of research, and by the extension of this mode of inquiry to new fields. Inventing instruments for observing, setting up experiments, measuring, and testing brought science again into intimate touch with the practical arts. Investigators took a keen interest in current affairs, sought to profit by the skill of craftsmen, and to put what they learned to practical uses. Discoveries were applied not only to the production of goods, but also to navigation, fortification, ballistics, and administration. By the close of the seventeenth century the dramatic achievements of 'natural philosophy' were leading many to expect an almost limitless advance, and the promotion of science was recognized as a proper object of public policy. Kings lent their patronage to scientific societies. Philanthropists followed the royal precedents by offering prizes for improvements in the arts and later by endowing research.

Of course the public relations of science were not uniformly harmonious in this age of genius. But the celebrated clashes between scientific discoveries and beliefs held by churchmen did not affect many lines of inquiry and did not gravely retard the rising tide of investigation. Not less characteristic of the age than Galileo's troubles were Newton's services to churchly teachings and to the State. Scientific men have lamented that he devoted his later years to arguing the validity of biblical prophecies; they have paid less attention to his work as Warden of the Mint. It was adjustments in the weights of the guinea and the shilling suggested by Newton that gave England a *de facto* gold standard in the eighteenth century.

An even more striking example of close relations between research and service to mankind is the life of Benjamin Franklin. The foremost American discoverer of his time, he was foremost also in applying and disseminating science to make life more comfortable, more secure, more interesting, more humane. These activities were incidents in the life of a busy printer, editor, politician, postmaster, legislator, colonial agent, and diplomat. But while we wonder at the extraordinary versatility of a man who could become both a scientific discoverer and a great statesman under any conditions, we must remember that in Franklin's day science was still in its 'natural philosophy' stage.

---

* From the address of the retiring president of the American Association for the Advancement of Science, delivered on December 27 at Columbus, Ohio.

With the cumulation of results, science became a more exacting mistress, requiring of her votaries more exclusive attention. But science did not draw away from the material tasks of daily life as it had in Greece. On the contrary, these relations were becoming more intimate, while scientists were learning to speak symbolic dialects less and less intelligible to the public or even to one another. Let me illustrate the seeming paradox by the relations between science and industry.

To most of us the modern age is characterized by technological progress as markedly as by scientific discovery. We think of the two achievements as interdependent. This interdependence was less obvious to Franklin's contemporaries than to us. Theirs was a century of great inventions, but inventions made mostly by men not trained in science. The captains of industry who carried the Industrial Revolution through its youthful phases were often technical experts, business executives, and capitalists united in one person. Men of this versatile type are still to be found even in 'big business'; but they are becoming as rare as once they were common. For, as technology was elaborated, experts with special training were required to supervise its operations.

The economic results produced by this unplanned organization of mutually stimulating activities astonished mankind. Industry after industry reorganized its processes time and again to take advantage of the latest engineering applications of scientific discoveries, and new industries kept cropping up. The efficiency of human labour increased greatly, *per capita* income rose, and hours of labour declined. Higher standards of living, and applications of science to the prevention and cure of disease, reduced death-rates and prolonged the average duration of life. Population grew rapidly in the nations that led the scientific procession, and spread where it would over the earth, dominating, exploiting, sometimes exterminating the non-scientific peoples. Life became ampler if not easier for the beneficiaries of science.

What industry owed science it repaid in many ways. It provided in bewildering variety laboratory equipment more accurate and powerful than that made by hand. It stood ready to construct any new contrivance an investigator designed, and often improved upon the original plans. Fortunes accumulated in business were the source of many scientific endowments. Business corporations granted research funds to universities, and set up research staffs of their own, which were sometimes permitted to work upon fundamental problems.

Governments recognized the social importance of science by making place for an expanding array of scientific courses in public schools and universities, and by undertaking wide-ranging programmes of research. In the United States, the Federal Government became the largest employer of scientific men. At the time of the Civil War it chartered the Academy of Sciences, and in the War of 1914–18, the National Research Council to advise it upon scientific problems; in 1934, it set up the organization that has developed into the National Resources Planning Board, with affiliations covering the full gamut of the sciences.

Finally, the public at large had a share in these great changes. It was the ultimate beneficiary of reductions in costs of production, of increasing *per capita* output, of new types of consumers' goods, of shorter working hours, of better protection against disease, of free education.

In short, this policy of *laisser-faire* worked wonders. Science helped industry and industry helped science. Even the backward art of agriculture, which faces so many difficulties and uncertainties, was benefiting by research. The dreaded 'law of diminishing returns' seemed to be overbalanced by improvements in practice based upon the work of soil chemists, botanists and geneticists. The frightful prospect of overpopulation that Malthus had taught the thoughtful to fear seemed to be dissipated by scientific agriculture and scientific techniques of contraception. Best of all, science seemed to have found the secret of illimitable progress.

II

I doubt that any scientist ever accepted without qualification this idyllic version of the benefits science confers upon mankind. Certainly there were numerous protests from scientific quarters against misuses of the new technology. Geologists and economists warned against the rapid depletion of mineral deposits. Chemists feared for the nitrogen content of the soil. Geographers and meteorologists protested that wholesale cutting of forests and the ploughing of grass lands produced deserts. Biologists lamented the extinction of animal species and anthropologists the callous stamping out of simpler cultures. Social scientists found much amiss within the countries that were most progressive. Urban and rural slums persisted as centres of disease and crime. The need of securing capital to utilize the new technology put control over it into the hands of the propertied classes. Labour was often grievously exploited. Huge fixed investments that could be used for only one purpose made competition destructive. The obvious escape from these hazards was to form monopolistic combinations. That was pleasant for the monopolists, but not for other business men or for consumers. Besides the obvious dangers of exploitation, many feared that the great combinations might purposely slow down technological advance because it threatened rapid obsolescence of their equipment.

Business did not manage even its own interests properly, for every few years it generated a crisis and depression in which it suffered along with the whole community ; and the international relations of the scientifically advanced peoples showed at his worst "the old savage in the new civilization". Demonstrations of the economic advantages of free trade no more stopped the imposition of protective tariffs than demonstrations of the horrors of war kept peace. Militant nationalism seemed to be spreading and growing more passionate. An appreciable fraction of scientific energy was devoted to contriving weapons of destruction. Thus against the glowing pictures of science as a benefactor of mankind could be set a dark picture of science putting more power into the hands of certain individuals, classes, nations, generations, giving them a differential advantage over others which they exploited according to their several natures.

Though some of the Jeremiads I have been recalling belong to an earlier time, they did not produce a profound effect upon the public relations of science until recently. The ills complained of could be regarded as 'growing pains'. They represented social 'problems', which should be dealt with by arousing public opinion in a campaign of education that would lead to remedial legislation. Problems that could not be solved by this time-honoured method would yield presumably to the slower processes of general enlightenment.

This optimistic attitude was particularly characteristic of democratic nations. It assumed tacitly that experts could devise whatever 'reforms' were needed, and that the majority of voters were intelligent enough to understand, and well disposed enough to support, desirable changes. Science had a stellar role in this programme for remedying the ills incidental to progress. It did not claim knowledge of good and evil ; but it enabled men to make their value-judgments more intelligent by tracing the consequences of actions. Many people were devoting their energies to the study of social problems ; they spoke optimistically of their subjects as social 'sciences'. It seemed not too much to hope that science might presently begin to guide social practice in somewhat the same fashion as it guided practice in industry and medicine.

III

That the public relations of science have recently become disturbing both to the public and to scientists is due, not to any change in the character of science or the behaviour of scientists, but to changes in social conditions. While most people approved on the whole of the applications of science before 1914, they have come to dislike many of the effects produced by later applications. To be specific : when scientific improvements in one industry after another threw men out of work in earlier decades, the victims might suffer in silence or protest riotously and perhaps smash machines. But the public at large was not deeply concerned over their sufferings ; it repressed disorder, expected the displaced men to find new jobs for themselves, and blessed science for reducing costs of production. Now that a larger part of the public suffers from loss of work or obsolescence of investments, science is blamed for technological unemployment. When the modern arts of communication were used to facilitate the political processes of democratic nations, they were extolled on all sides. Now that these arts, further improved, are controlled in some countries by autocratic Governments and used to suppress opposition, many good people treat science as the culprit. When the scientific nations used their superior arms against backward peoples, only a few sensitive souls were wrathful over the unfairness or iniquity of the procedure. Most people felt that science was good when it gave them a decisive advantage over those they wished to 'civilize'. Now that these same nations are threatened by still more terrible weapons in the hands of their peers, their moral horror is sincere, and they wish scientific warfare back to the pit from which it was digged.

This shift in attitude toward science as one happens to benefit or suffer from its applications is doubtless a mark of human frailty, but it is one at which scientists should not cavil without recalling a similar frailty of their own. Now that we are on the defensive, we discover that science is neither good nor bad in itself, but is merely an instrument that can be put to good or bad uses, and that the blame for bad uses should be visited upon those responsible for them. But when science was being lauded for good works, who among us argued that the credit belonged, not to science, but to those who used it for the benefit of mankind ?

We made this discovery when difficulties forced us to think more carefully about the place of science in society. Well as the old policy of *laissez-faire* in public relations worked for a time, it had encouraged in us an indolent complacency foreign to the critical spirit of inquiry. We may not enjoy the shocks that have aroused us any more than an investigator rejoices over facts that disprove an elegant hypothesis ; but we must face the situation and see what we can do to mend it. I venture to suggest an obvious proposition that seems to me of controlling importance, and to point out certain corollaries that should guide both our attempts to understand the public relations of science and our future policy concerning them.

IV

The fundamental proposition is that scientific research is a social process as much as business, political, or religious activities are, and as such is interwoven with all other social processes, influencing them and being influenced by them. It is one among many social activities carried on by the peoples of our culture. Like all such processes, it is carried on by men who learn in childhood languages ill-suited to close thinking; by men who wish to eat, to make love, to win approval as well as to know; by men who are reared in an environment of emotional likes and dislikes; by men who become so absorbed in their technical tasks that they have little energy to criticize the non-scientific parts of their own make-up. These scientific men form a tiny fraction of their communities. So far as they succeed in emancipating themselves from the misconceptions and prejudices prevailing in their social groups, they become by virtue of their partial emancipation queer creatures whose judgment most people mistrust outside of their specialties. Both the temperament that inclined them to research and the habits they form in research tend to make them awkward, ineffective, reluctant in appealing to the emotions that are so potent in influencing men.

It is difficult to see how a few scattered individuals, each accustomed to think for himself and to be critical even of his fellow inquirers, can guide public opinion except by slow educational processes. In the long run, their thinking may rule the world, just because it serves the purposes of mankind better than the traditional thinking it gradually replaces. But in the short run, others take of scientific discoveries only the parts that have an immediate application, and put these parts to such uses as they see fit—uses that serve whatever aims these others pursue. The prompt and potent influence of science upon society comes from these uses, good and bad, which scientists control only in small part.

Even in democratic countries, then, scientific men find it hard to bridge the gulf between their attitudes and those of the general public. In autocratic States the Governments might give scientists fuller opportunities to direct public policies than they enjoy in the democracies. But the autocratic States known to us are not built on that model. They are avid for science, to be sure, but only for science that is an uncritical servitor of ends the rulers determine. As between the difficult public relations confronting them in democracies and the shackling of free inquiry confronting them in autocracies, scientists cannot hesitate. Theirs is a world of intellectual freedom, not perfect alas, but the freest world the mind of man has yet created, and to let any authority under any pretence prescribe what conclusions they shall accept as scientific is to stultify the spirit of science.

V

What, then, can scientists do to improve their public relations in communities where they are relatively free ?

As I see the situation, they have two sets of opportunities and responsibilities; first, their opportunities and responsibilities as citizens; second, their opportunities and responsibilities as investigators.

What scientific men can do as citizens is like what other intelligent men can do. If democracy is to work well, many people must form considered judgments upon a wide variety of problems. In forming a considered judgment on a given issue, what experts have to say should be taken into account. Who these experts are depends upon the character of the issue; more often than not contributions are needed from several kinds of specialists. All the many species of the genus scientist belong at one time or another in the list of desirable technical advisers; so also do lawyers, business organizers, labour leaders, social workers, educators, civil servants, politicians, and so on. When matters within the competence of some group of scientists are involved, they should contribute what they know, whether formally invited to do so or not. To make their advice effective they should welcome help from people more skilled than themselves in the arts of popular presentation. On matters concerning which a scientist has no special knowledge, he should listen to others and form the best judgment he can from what they advise. To an individual this task of sifting and weighing different opinions is time-consuming and difficult. On complicated issues organization is needed to bring into focus all the intelligence available in the community. Hence one of the civic duties incumbent upon all scientific men in common with other citizens is to support vigorously but critically the nascent movement toward organizing all the intelligence we possess for constructive study of social problems, before they become pressing emergencies that have to be dealt with in a hurry that allows no time for careful thinking.

The outside limits of what scientists can accomplish as citizens are set by their ignorance. Not merely does no individual have more than a tiny fraction of the knowledge that is needed; all the scientists of the country put together do not know enough to solve many of the problems that a democracy faces. In addition to the responsibilities they share with all other citizens, scientific men have the special duty of trying to increase the kind of knowledge required to deal intelligently with public problems. Their opportunities and responsibilities as citizens merge into their opportunities and responsibilities as investigators.

From the social point of view, the most urgent item in the unfinished business of science is to increase knowledge of human behaviour. If we had keener insight into individual psychology, we might not be able to alter fundamental drives, but we might be able to direct them into beneficent channels. Preaching righteousness doubtless prevents men from being as bestial as they might otherwise become. Appeals to reason prevent them from making as many errors as they otherwise might. But the moralist and the rationalist admit that the results of their efforts are grievously disappointing. Scientific men with any gift of self-analysis realize that they have their own shares of selfishness and animosities. To subdue traits in oneself is hard enough to give an inkling of the difficulty of controlling them in society at large. Perhaps—and perhaps is all we can say—if we can come to a clearer understanding of how we behave, we can learn how to condition men so that their energies will go less into making one another miserable.

We all know that the social sciences lag far behind the natural sciences. That is because they deal with phenomena more complicated, more variable, and less susceptible of experimental manipulation. Since social investigators cannot experiment at will upon social groups, they cannot effectively apply to their problems the methods that have made the laboratory sciences strong.

Yet the case of economics and its sister sciences is not hopeless. The rapid growth of statistics is providing mass observations upon social behaviour of many kinds; the equally rapid growth of statistical technique enables us to learn more from a given array of data than our predecessors could. These materials and methods are making it possible to measure many social factors, some rather accurately, some roughly. Uniformities appear not only in averages, but also in the way in which individual items are distributed about their means. Statements in terms of probability can be substituted for vague statements about the effect a certain cause 'tends' to produce. True, work on this observational basis encounters many difficulties. It is limited by the variety, extent and accuracy of reliable data upon human behaviour. It is laborious, slow and expensive. In presenting his work a realistic investigator begins with a critique of his data and methods; he ends by setting forth the probable errors and limitations of his results. and the road from the beginning to the end may be long. Instead of definitive conclusions he thinks others should accept, he presents tentative approximations he expects others to improve. The work has not even the advantage of calling for less hard thinking than speculative theorizing; for the relations among the variables in the problem are seldom manifest of themselves. All that can be claimed for this type of work is that it deals with actual experience, that its results stand or fall by the test of conformity to fact, and that it grows cumulatively after the fashion of the observational sciences. But that is enough to give mankind strong reason for following this lead in seeking the knowledge required to improve social organization.

But science cannot flourish in the future and yield the fruits for which we hope unless freedom of thought prevails. The democratic way of life and the scientific way of thinking grew up together, each nourishing the other. If one now fails, the other will falter. Where democracy is suppressed to-day science is fettered; for autocracy cannot brook disinterested criticism of its dogmas or its practices. Freedom of scientific work in the years to come can be guaranteed only by preserving the institutions that secure freedom to all citizens.

Perhaps scientific men have more at stake than any other social group in the struggle to maintain democracy. To this struggle they can make a crucial contribution. The fact of free societies hangs upon the wisdom or folly of mass decisions. The gravest dangers to democracy come from within, not from without. They are ignorance, and propaganda that turns ignorance to its uses. The best way of dispelling ignorance is by diffusing knowledge. The most effective defence against meretricious propaganda is critical inquiry. John Dewey is warranted in saying that "the future of democracy is allied with spread of the scientific attitude". To foster this attitude among their fellow citizens by all means within their power is a duty incumbent upon us who cherish science. As teachers in schools and colleges we can help thousands to develop respect for evidence. As citizens we can be brave opponents of prejudice and hysteria. We can promote general understanding of the methods and results of science through our own writings or those of allies more skilled in popular exposition. These things we should do, not as high priests assured that they are always right, but as workers who have learned a method of treating problems that wins cumulative successes, and who would like to share that method with others.

A NEW APPLICATION OF ECHO-SOUNDING

BY DR. C. H. MORTIMER AND DR. E. B. WORTHINGTON,

FRESHWATER BIOLOGICAL ASSOCIATION, AMBLESIDE

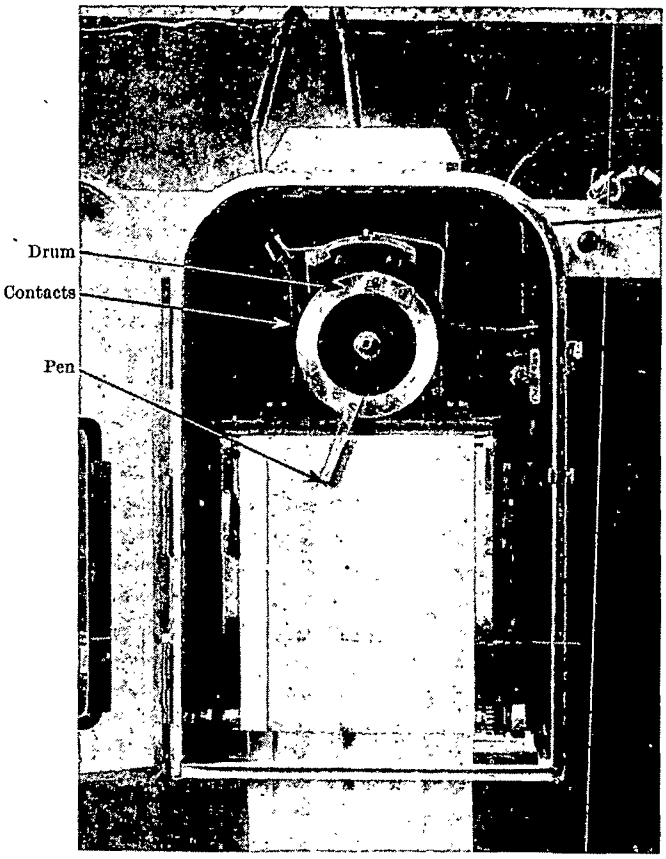

Fig. 1.
THE HENRY HUGHES ADMIRALTY PATTERN ECHO-SOUNDING RECORDER.

BY 1937 the biological researches at Wray Castle had reached the stage when a detailed bathymetric survey of Windermere was desirable as a basis for studying features of the lake bed. The Hydrographer to the Admiralty kindly agreed to co-operate on the technical side, and a survey was carried out by Lieut.-Commander Farquharson, of the Admiralty's hydrographic staff, using a magneto-striction recording echo-sounding machine of Admiralty pattern manufactured by Messrs. Henry Hughes and Son, Ltd. The main feature of the recorder (Fig. 1) is a drum which is rotated at a constant speed by an electric motor. An arm attached to the drum carries a metal 'pen' which traces the record on paper moistened with solution of potassium iodide and propelled slowly through the machine. Contacts on the drum are arranged in such a manner that a supersonic sound impulse is transmitted from an oscillator, below the surface of the water, for an instant when the revolving pen has just begun its transit across the paper. The sound impulse, directed downward, is reflected from the bottom, is picked up by a receiving oscillator also mounted in the water, is amplified and passed to the pen. The rises in voltage at the pen point, consequent on the transmission and return of the signal, cause electrolysis of the potassium iodide and produce brown stains of iodine on the paper—one, the zero mark, at the instant of transmission, and the second on the reception of the echo. The distance along the arc of the pen's track between these two marks represents the depth of water, and the process, repeated at each revolution of the drum, gives a continuous record of depth. The whole equipment, consisting of the recorder, amplifier, oscillators and 12-volt accumulator, can be mounted comfortably in a small launch or rowing boat.

In the survey of Windermere 260 cross-sections, representing some 150 miles of continuous sounding, were recorded during five weeks, and the measurements of depth were afterwards made available by the Admiralty on the 6 in. to a mile scale, with certain areas in greater detail on 25 in. to a mile maps. The results of this survey, sufficiently valuable in the information they provided regarding the depth of water, proved to be of much interest in quite another way. Many of the records not only showed an echo from the floor of the lake, but also a second, though fainter, echo, and sometimes more, at vertical distances (measured on the records) of up to 13 metres below the lake floor. It is known that much of the lake bottom is covered by soft mud of considerable depth, presumably overlying rock or glacial clays which formed the floor of the lake at the conclusion of the Ice Age. Therefore, it seemed that the double echo shown on the records could be explained on the assumption that only some of the sound waves transmitted by the machine were reflected from the interface between mud and water, and that others penetrated the waterlogged deposits and were reflected by the harder glacial clay or solid rock underneath. In other parts of the lake (*A* in Fig. 2) the bottom appeared as an intense black mark with one or more fainter marks below, at apparent distances below the bottom equal to the depth of water. In such cases it seemed justifiable to assume that all the sound waves were reflected from a hard bottom and that, since an air-water interface reflects supersonic sound, they were afterwards re-echoed to and fro between the surface and bottom. If these interpretations were correct, the echo-sounding machine could be used to give information regarding the kind of bottom and the depth of soft deposits. Accordingly, the research was followed up by (1) making observations on the deposits themselves, and (2) carrying out surveys with the echo-sounder on fourteen other of the larger lakes in the district.

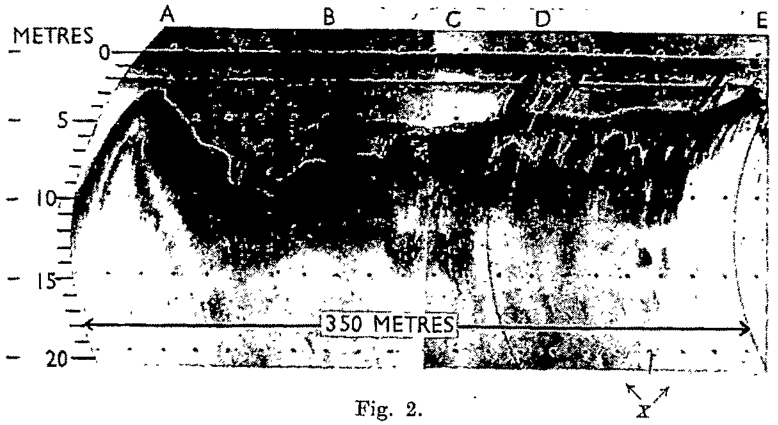

Fig. 2.
Echo-record of a section across Low Wray Bay, Windermere.
X are time marks recorded every thirty seconds.

In the first of these projects, sections such as that shown in Fig. 2 were examined and it was confirmed by the use of lead and grab that at *A* the bottom is bare rock, at *B* it is soft mud, at *C* stiff clay overlain by a thin deposit of soft mud. At *D* beds of water weed (Potamogeton) growing in the mud were under the oscillators as the superficial marks made their appearance on the record, and at *E* a stony bottom could be seen through the shallow water. Direct measurements of the actual depth of soft deposit were made with a probe of special design constructed by Dr. J. A. Ramsey of Cambridge. Of twenty-one such measurements made under favourable conditions, all showed depths which agreed to within a foot with the depth of deposit as indicated on the echo records. In addition, cores of the deposits have been obtained from some parts of the lake, first with a simple tube driven into the bottom and later with a special core-sampler described previously[1]. The examination of cores is important because many of the echo-records (for example, at some points in Fig. 2) indicate stratification of the deposits. Moreover, the cores throw light on the post-glacial history of the lake basin: they show fine varving in the deposits, and there is an alternation between periods in which inorganic, probably ice-eroded, particles are predominant with periods when the bulk of the deposit is made of the shells of diatoms. The succession of diatom and other organic remains in these cores is being studied by Miss W. Pennington of the University of Reading.

The surveys of other lakes, made by members of the staff at Wray Castle, serve to confirm the main bathymetric features as determined by H. R. Mill[2].

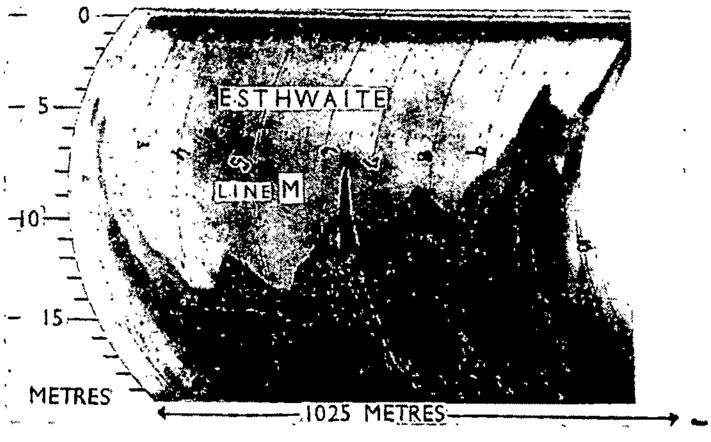

Fig. 3.
Echo-record of section across Esthwaite Water.

These surveys were not of the same detail as that of Windermere, but sufficient sections were recorded to obtain a good idea of the bottom characters. The photograph of a representative record from Esthwaite Water, reproduced in Fig. 3, shows a mound of hard bottom projecting through an even layer of soft deposit. Over the rest of the section the thickness of soft deposit is roughly uniform and the mud profile follows in smoother outline the irregularities of the hard floor below. In other cases, for example at *D* in Fig. 2, such irregularities are masked by a level blanket of mud. Fig. 4 shows another type of sedimentation in a region—the narrows joining the north and south basins of Windermere—in which an appreciable water flow is to be expected. The figure shows a scoured channel on one side with a mud bank on the other, a condition which might be expected from the configuration of the locality. A more complex kind of sedimentation, in which the deposit appears to be divided into a series of strata, is suggested by other records. All these types of record have been exactly reproduced over the same positions at different times by two recorders having differences in the details of construction, and recording on different scales.

It must be emphasized that further direct observations on the deposits are required before the interpretation of the echo-records can be accepted without reserve. The speed of travel and the penetration of supersonic sound in water-logged deposits have yet to be determined, and the nature of the interfaces from which it is reflected awaits investigation. But it seems probable from the results mentioned above that the echo-sounding machine provides a means of measuring the result of subaqueous deposition over long periods of time. Such measurements would be of practical use in connexion with reservoirs and harbours where the deposition of soft deposit on a hard floor often takes place rapidly. They would also be of much interest to hydrographers, geologists and limnologists. For example, in each lake so far examined, the total volume of soft deposit, as computed from the echo-records, is found to be related to the size and character of the drainage basin. This is illustrated in the accompanying table of values for selected lakes.

	Mean depth of water (metres)	Mean depth of deposit (metres)	Volume of deposit (10^6 cubic metres)	Drainage area (sq. km.)	Volume of deposit / Drainage area	% drainage area on uncultivated hills
Haweswater	12·0	0·52	0·7	29·1	2·4	92
Ennerdale Water	18·9	0·88	2·5	44·1	5·7	94
Coniston Water	24·1	1·09	5·4	60·7	8·9	78
Windermere	23·8	1·62	24·1	230·5	10·5	70

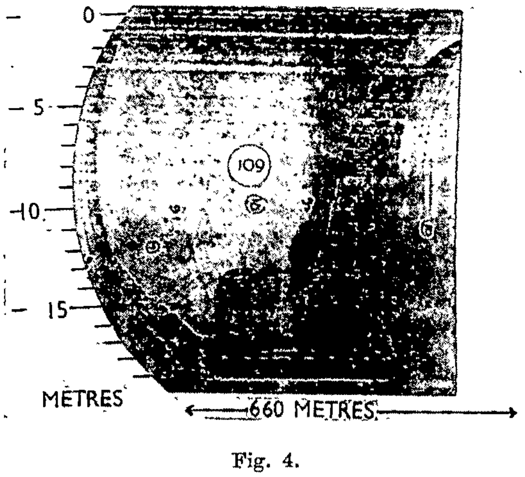

Fig. 4.

ECHO-RECORD OF SECTION NEAR THE FERRY, WINDERMERE.

The figures in the last column but one represent the depth of deposit in centimetres if it were spread evenly over the whole drainage basin, and may be regarded as an index of silting rate. Pearsall[3] showed the controlling influences of the silting rate on the distribution of aquatic plants; his classification of the lakes of the district on this basis is corroborated by the new data from echo-sounding.

Since the work described above was carried out, the work of Stocks[4] and Rust[5] has been brought to our notice. Using a different type of non-recording echo-sounder in Kiel Bay, they obtained double and multiple echoes over soft bottoms in contrast to single echoes over hard bottoms, and they put forward an interpretation similar to the one advanced here.

We are much indebted to Messrs. Henry Hughes and Son for the loan of echo-sounding machines and to those scientists who have given help in the work. A fuller account of the surveys is being published elsewhere[6].

OBITUARIES

Prof. F. K. Richtmyer

THE death of Prof. Floyd K. Richtmyer on November 7 has removed a notable figure from scientific circles in the United States. Born in 1881, he graduated at Cornell, most of his academic life being spent as a member of the staff of this same University. His doctoral dissertation was on the subject of photoelectric phenomena, and studies on physical photometry occupied several years of research, during which time he worked under the guidance of E. L. Nichols.

During the War of 1914–18 the urgent need of optical information and instruction in connexion with the development of military instruments and with numerous problems of vision not only led to the rapid growth of the Optical Society in London but also to the foundation of a strong sister society in America. Dr. Richtmyer, appointed in 1918 to a full professorship at Cornell, was a leading figure in the American Society from the beginning, and played a most important part in the subsequent development of the American Institute of Physics.

At various times he was elected to the presidency of the Optical Society of America, the American Physical Society, and the American Association of Physics Teachers. He was associate editor of the *Journal of the Optical Society* from 1917 onwards, and in 1932 he became editor-in-chief of the *Journal* and the *Review of Scientific Instruments*. In the same year, he was elected to the National Academy of Sciences.

Anyone who knows the characteristically friendly meetings of the Optical Society of America, held fairly frequently at various centres in the States, will fully appreciate the careful organization that must have been carried out by a group of which Richtmyer was one of the leading figures. His careful and thorough work as editor of the *Journal* has benefited many who appreciate the high standard which is maintained in its pages. Perhaps he is best known to present-day students of physics through his text-book "Introduction to Modern Physics", in which his great gifts as a teacher and expositor are reflected.

In recent years Richtmyer had many administrative duties at Cornell, that most pleasant of universities with its tree-shaded campus high above the blue waters of the Senaca Lake, but he found time to direct the studies of a class of graduate students in a laboratory where the atmosphere is progressive and stimulating. His chief recent interests lay in the fields of X-rays and spectroscopy, and many papers have borne witness to his thoroughness and care in experimental work.

The many in the United States who relied on Richtmyer's judgment and experience will miss him greatly and their regret will be shared by many in Great Britain who had the privilege of meeting him.

L. C. Martin.

Mr. G. Herbert Nall

The death of Mr. G. Herbert Nall at the age of seventy-nine years occurred on January 14. Mr. Nall was educated at Shrewsbury and at Queen's College, Oxford, where he took a second class in Classical Moderations (1881) and in Lit. Hum. (1884). He was appointed lecturer in Queen's College in 1884 and was classical master and librarian at Westminster during 1886–1922. He was housemaster of the Home Boarders from 1895 and edited many books of the classics for use in schools.

As well as being a classical scholar, Mr. Nall had a bent for natural history which was developed by angling in Great Britain and the Scandinavian countries while he was at Westminster. After he retired he took up the scientific investigation of the life of freshwater fish and in particular of sea trout and trout. Working under the auspices of the Fishery Board for Scotland (now the Fisheries Division of the Scottish Home Department) he applied the technique of scale reading to, and became the recognized authority on, this species. As his work developed, it became clear that the life-story of the sea trout was more complicated and liable to greater variations than that of the salmon, and if a true picture was to be obtained an extended and detailed investigation would be necessary. This laborious task Mr. Nall attacked wholeheartedly. In spite of the size of the undertaking he was never daunted by detail and never thought any trouble too great in order to be sure of his material or of the facts which he elicited from it. His main work was in Scotland, but in addition he did much in England and Wales: he also did not omit Ireland and certain European countries from the scope of his survey. He finished his fortieth paper (publication of which will unfortunately be delayed by the War) for the Scottish fishery department a few minutes before he died. Many other papers by him were published in various journals. His latest work did nothing to disturb his conclusions reached a few years ago, and his "Life of the Sea Trout" will for long remain the standard work on that subject. It is not too much to say that our very complete knowledge of the life-history of the sea trout is due almost entirely to his efforts.

In the death of Mr. Nall, freshwater fishery research in Great Britain, and particularly in Scotland, has lost an enthusiastic and painstaking worker who has accomplished much. In his passing those who knew him have lost a quiet, humble soul and one who never failed to help others.

We regret to announce the death of Sir Gilbert Morgan, O.B.E., F.R.S., formerly director of chemical research, Department of Scientific and Industrial Research, on February 1.

NEWS AND VI

Two Eminent Swedish Chemists

THE year 1840 saw the birth of the two Swedish chemists, Per Theodor Cleve and Lars Fredrik Nilson, the former of whom was born at Stockholm on February 10. Cleve was the son of a merchant, Nilson the son of a farmer of Ostergothland. Both of them became students at the University of Uppsala, where they came under the influence of L. F. Svanberg, who had been the friend of Berzelius. After graduating, and teaching chemistry at Uppsala, Cleve worked in Wurtz's laboratory in Paris, and in the mineralogical laboratory at Stockholm; he then made a geological excursion to the West Indies. After his return home, in 1870 he was given a post at the Stockholm Technical Institute, but on Svanberg's retirement became professor of chemistry at Uppsala and held this position until shortly before his death. Like his contemporary Nilson, he did valuable work on the rare earths, and he showed that scandium, the element discovered by Nilson, was identical with the eka-boron of Mendeléeff. It was partly for his work on the rare earths that he was in 1894 awarded the Davy Medal of the Royal Society. Towards the end of his life he became absorbed in biological studies. For the Chemical Society, of which he was a foreign member, he wrote the memorial lecture on the Swiss chemist J. C. G. de Marignac (1817–94). He died at Uppsala on June 18, 1905.

While Nilson was also known for his investigations on the rare earths, he rendered great service to his country as an agricultural chemist. Farming was in his veins, and he always retained an interest in the prosperity of his native district. After holding the chair of analytical chemistry at Uppsala from 1878 until 1883, he was called to Stockholm as professor of chemistry in the Royal Academy of Agriculture. In the next sixteen years, while engaged on his official duties, he published nearly sixty papers on soils, manures, etc., and his inquiries led to the draining and cultivation of the swamps of Gothland, and to the introduction of the sugar beet. He was elected a foreign member of the Chemical Society in 1888. He died on May 14, 1899, in his fifty-ninth year.

The Parliamentary and Scientific Committee

A MEETING of the Parliamentary and Scientific Committee was held at the House of Commons on January 31. In the absence of the chairman, Captain D. F. Plugge, M.P., the chair was taken by Major H. A. Procter, M.P. The Secretary announced that the following bodies have now definitely agreed to support the new Committee: Association of Scientific Workers, Institute of Chemistry, British Association of Chemists, National Veterinary Medical Association, Institution of Structural Engineers, Institution of

Nations began in 1920, and in 1921 it became part of the permanent secretariat of the League, with offices in Geneva. The Section consists of three divisions, namely, a directing committee, a consulting committee of experts consisting of the directors of the International Health Office, and an executive staff composed of public health experts, statisticians and clerks who devote their whole time to the work. The Section has done valuable work in the control of epidemics, the standardization of medical procedures, and the collection and publication of medical information.

engineer to Carlisle, is published describing an effective and easily applied method of thawing frozen water services, when a public A.C. supply is available. In Carlisle, where the voltage is 230, a double-wound single-phase transformer is used, the ratio being 230/12, with a regulating resistance on the primary side and an ammeter scaled 0–250 on the secondary side. The primary is plugged into a 15 amp. radiator socket and the secondary leads are attached to a tap or pipe inside the house and to the stopcock of a neighbouring house. The regulating resistance is adjusted until the secondary current flows through the frozen pipe at about 150 amp. It is found that the normal $\frac{1}{2}$-in. lead service pipe thaws out in five to seven minutes. Mr. Salt says that in cases of sickness where there is no water supply and consequently no kitchen fire or other means of providing hot water, this remedy has been much appreciated.

New Physical Apparatus

Prof. C. J. Overbeck of Evanston University, Illinois, directs attention to some of the recent improvements in apparatus for physical research developed in the United States during the last four years, in a twelve-page illustrated article in the January issue of the *Journal of Scientific Instruments*. He deals with fractionating oil-diffusion pumps of both glass and metal and with the use of sylphon (metal bellows) for producing adjustments in evacuated spaces from outside without interfering with the vacuum. He describes a centrifuge suspended and run in a vacuum, a new apparatus for determining e/m for electrons, and a device for renewing the emitting surface of an oxide cathode. The Bureau of Standards apparatus for attaching to free balloons which signals its records and weighs only 5 lb. is also mentioned. Some examples of the use of Polaroid for stress analysis are given, and a vacuum grating spectrograph for investigating infra-red rotation spectra is described. The advantages of the new synthetic lithium fluoride crystals combined with quartz in a lens doublet, achromatic over a wide range of wave-lengths, are illustrated by spectrograms. References to thirty-one sources of further information are given, and Strong's "Procedures in Experimental Physics" (New York, 1938) is mentioned as of great value for its up-to-date laboratory devices.

Seedlings in Transit: a New Method

Science Service, of Washington, D.C., reports the extensive use of a new and simple method of protecting young seedlings of tomato and cabbage from drying out during transit, which may have considerable importance in Great Britain at the present time. Dr. R. N. Du Puis of Chicago suggested that the plants might survive better if the sphagnum in which the roots were wrapped were moistened with a glycerine solution instead of with water. After encouraging large-scale experiments in 1939, the method was brought into commercial use, more than 75 million seedlings being shipped from the south to the north under these conditions. The new method apparently saved much loss from drying out and is also stated to give protection against fungus troubles.

The National Book Council

It was a wise statesman who said that we must educate our masters, the democracy of to-day, and the National Book Council's latest report, 1938–39, is full of a well-backed forward movement with a new Consultative Committee designed to promote more book-reading. At present, the public libraries are used by about 15 per cent of the population, which remain in ignorance of the chances they have to improve their knowledge, or at least get sound information about their hobbies and the special line of reading they prefer. "Four to Fourteen" for young people has already become a standard bibliography, and "Summer Holiday Reading", a select list of new books, has led to demands beyond the large number printed. Such guides through the present overgrown jungle of books are essential to-day.

The 38-page "Catalogue of Books for the Services" is a good and wisely catholic selection, due to the Council and the Society of Authors acting together. It gives learned and popular theology on one page and on another a choice of thrillers by Dorothy Sayers, science, plays, essays, and fiction, old as well as new. We notice one omission in the judicious section of poetry; Kipling's two early books of soldier jingles are included, but where is the "Collected Verse" of his more mature years? That volume holds many well-known pieces and celebrates the work of our Navy with the "Wet Litany", "Mine Sweepers", "The North Sea Patrol" and other vivid things not easily forgotten. Evacuees, both young and adult, have raised new problems of book-supply, in towns and villages unequal to the demand, and the Council has suggested to the Board of Education sound plans to arouse interest and supply the books needed.

Earthquakes in Greece

Strong earthquakes were experienced last week in the town of Ekaterini at the foot of Mount Olympus on the shores of the Gulf of Salonica in Greece. On the morning of February 1, several tremors and one or two earthquakes occurred to the accompaniment of loud and long-continued underground rumbling. Some houses collapsed. On February 2 the shocks continued, there being eighteen in all. About 120 buildings, including some schools, the law courts and the post office, collapsed or became severely damaged. The casualty numbers have not yet been published. Tents have been erected as temporary dwellings and the postal headquarters are reported to be temporarily in a tent. Medical supplies and anti-typhoid vaccines have been sent from Salonica. It will be remembered that a severe earthquake wrecked several villages in the Chalcidice district of Greece on the night of September 27–28, 1932. The epicentre was then estimated to have been between Salonica and Mount Athos (Nature, October 8, 1932, p. 537), which is to the north-east of the present epicentres.

Earth Tremors in Scotland

Slight earth tremors are reported to have occurred on February 3 at Stirling in Scotland. No damage has been done. The tremors may have been occasioned by slipping along a local fault. Similar tremors were reported from Roslin, near Edinburgh, on February 10, 1934, though the most active region seismically in Scotland is near Comrie in Perthshire, where the slight tremors are considered to be due to slipping along the Highland Boundary Fault system.

Other Recent Earthquakes

SEVERAL severe earth tremors and moderate to strong earthquakes have also been experienced recently in widely separated areas in Italy. On January 25 a severe tremor was felt at Genoa in Italy. This did no damage. On February 1, early in the day, a severe earthquake shock caused considerable damage to the famous cathedral town of Siena in Italy. A less severe shock was felt at Florence, and, presuming it was the same earthquake, the epicentre was close to Siena (lat. 43° 20′ N., long. 11° 20′ E.) On the same morning three shocks were felt in Bucharest, in Rumania. No damage was done. The epicentre of this earthquake was estimated in Bucharest to have been in the Black Sea, five hundred miles east of Bucharest.

Earthquake Recorded on Magnetograph

IN *Earthquake Notes*, the publication of the Eastern Section of the Seismological Society of America (11, Nos. 1 and 2, September 1939), it is stated that the earthquake with epicentre latitude 20·8° N., longitude 66·0° W. on June 12, 1939, which was felt in San Juan, was recorded at the San Juan Magnetic Observatory. The recording was on the magnetograms of both the declination and the horizontal intensity instruments, but there was no trace of a disturbance on the vertical intensity magnetogram.

Francis Amory Septennial Prize

IN compliance with the provisions of the will of the late Francis Amory, the American Academy of Arts and Sciences, as trustee of a fund given by the testator, announces a prize to be known as "The Francis Amory Septennial Prize", to be awarded for conspicuously meritorious work performed during the immediately preceding septennial period, "through experiment, study or otherwise, in the treatment and cure of diseases and derangement of the human sexual generative organs in general, and more especially for the cure, prevention or relief of the retention of urine, cystitis, prostatitis, etc." If any work of quality warrant it, the first award will be made in 1940. The total amount will exceed 10,000 dollars, which may be divided at the discretion of the Academy among several nominees. While formal nominations are not expected and no essays or treatises in direct competition for the prize are desired, suggestions are invited. Communications should reach the Francis Amory Septennial Prize Award Committee not later than May 15, 1940, and should be addressed in care of the American Academy of Arts and Sciences, 28 Newbury Street, Boston, Mass., U.S.A.

Paris International Trade Fair

THE thirty-second annual Paris International Trade Fair will be held during May 11–27. The international aspect of the Fair will be developed to an even greater extent this year. Already national sections have been promised from Italy, Holland and Spain, as well as the usual displays from Switzerland, Belgium, etc. In deciding to hold the Fair this year

For each date we have chosen as abscissa the number of cases for each given height, and as ordinate the height in kilometres. The time is central European time.

As will be seen, the height was greatest on December 30, 1926, mean 27·7 km., and on January 29, 1932, mean 27·4 km. Of special interest is the fact that the clouds during the night of February 19–20, 1932, were lower down than in the afternoon on February 19, with a difference of 1·6 km. between the means.

RESEARCH ITEMS

Gypsy Luck in Serbia

THE function of luck among Serbian gypsies is formulated as follows by Alexander Petrovič in his continuing study of their beliefs (*J. Gypsy Lore Soc.*, Ser. 3, 19, 1–2; 1940). As they have no personified god, *O Del* (heaven) gives, and *Kar* (lingam) creates, but it is *Baχ* (luck) which gives to man the ability to use what these give and create. Some gypsies believe that Good Luck is a pretty girl, a nymph living in the woods, while Bad Luck is an old man or a toothless old woman, but the Serbian gypsies understand *Baχ* rather as some property of a man, animal or object. He who possesses such a capacity brings luck into the home, and this means health to the household and progress and success in every venture. In a household the wife's luck is the most important; and if a man is unsuccessful in business it may be the fault of his wife, and he may change the luck by being temporarily unfaithful to her. Luck may attach to the bag which a woman carries on her begging expeditions. One woman had had fourteen bags of which only the first was lucky. She always kept a scrap of rag from this one and carried it about with her. Luck may also reside in a whip or an article of clothing. If things or people are not luck bringers they may obtain this power by blessings, as when a wife throws water over her husband as he starts on a journey, saying, "Good luck to thee on thy way", or when a smith begins to use a new hammer and his neighbours say, "May thy hammer be lucky." In the same way certain persons, animals, things may bring bad luck (*Bibaχ*). If a child is unlucky it must be avoided. It must not pour water on you in the morning or talk to you early in the day. It should not approach the anvil, nor should tools be put in its hand; and if a boy it must not become a smith.

Maori Bowls

UNLIKE the Melanesians, the Polynesians never acquired the art of making pottery, but used as receptacles for a wide variety of purposes wood, supplemented to a certain extent by gourds and baskets of totara bark. The general style and perfection of finish of Polynesian and Melanesian wooden bowls vary considerably with different localities. The most perfect come from Hawaii. The Maori bowls show great variety of form, ranging from crudely hollowed out logs to beautifully finished examples, ornamented with carving. Some agree very closely in *motif* with Hawaiian bowls, while others have a distinctly Melanesian character. The collection of Maori bowls in the Auckland Museum, New Zealand, comprises more than forty examples. These have been described, with others not in the collection, but included for comparative purposes, by A. G. Stevenson, assistant ethnologist of the Museum (*Rec. Auckland Inst. Mus.*, 2, 4; 1939). The specimens are divided roughly into five classes mainly according to shape: long, trough-like bowls, short, broad and usually deep bowls, bowls of approximately equal length and breadth, the rim outline being between a square and a circle, bowls in which the bottom internally is flat, while externally they are hemispherical with or without a flat hemispherical base, and in the fifth class two bowls of distinctive type, one almost circular in outline on a small flat oval base, and the other in which the rim is almost circular, but thickens out to a point externally at each end. There are also a number of bowls of unusual form. The bowls, being primarily for use, are not ornamented as a rule, but there are notable exceptions, in which handles or spouts are carved to represent conventionalized human faces. Most of the bowls were of totara wood; but immersion in swamps over a prolonged period often makes exact identification of the wood impossible.

East Indian Gastropods

Drs. Adam and Leloup, in "Résultats scientifiques du Voyage aux Indes Orientales néerlandaises de LL.AA.RR. le Prince et la Princesse Léopold de Belgique" (Mém. du Musée d'hist. nat. de Belg., Bruxelles, 2, Fasc. 20; 1939), have concluded their study of the gastropods. The present volume deals with pulmonates, scaphopods and bivalves. There are five text figures, seven plates of shells and a map showing localities. The résumé of all the molluscs found, with localities, will be useful to collectors. Altogether nearly six hundred species are listed, but of these only a small number, comprising one amphineuran, one opisthobranch and seven pulmonates are new. This volume contains the last twelve families of pulmonates and one new species, *Ptychodon misoolensis*, which is not described, as an account of it appears elsewhere. The work is systematic and deals with shells and radulæ.

Fossils from the Belgian Ordovician

IN "L'Ordovicien de Sart-Bernard" (Mém. 86, Mus. Roy. d'hist. nat. de Belg., Bruxelles, 1939) E. Maillieux describes the fossils extracted from the Arenigian and Llandeilian strata of Sart-Bernard. There are three plates. From the Arenigian, graptolites, Lingula, trilobites and the Nebalian Lamprocaris are described, and resemble those of other Belgian rocks of the same age. From the Llandeilian one brachiopod, Pionodema, gastropods, lamellibranchs and trilobites are listed. As a whole the species are those peculiar to the Ordovician of Bohemia, except for *Conularia rugulosa*, which occurs also in Normandy, and the two species *Liospira œqualis* and Tentaculites n.sp. which have not been found in Bohemia. The first is a Scottish species. The two Belgian specimens of the second were unfortunately imperfect, so that no specific name is given to them.

Leaf-Growth as a Systematic Feature in Ammocharis

Milne-Redhead and Schweickerdt (*J. Linn. Soc.*, 52; 1939) have re-investigated the systematic position of the genus Ammocharis and related genera, especially Crinum. Whilst some species of

Crinum are readily distinguished by spiral leaf arrangement, others have distichous leaf arrangement as in Ammocharis, but the leaves are always sheathing at the base and are never biflabellately arranged. A peculiar feature of the leaves of Ammocharis, earlier described by Herbert, is that the leaves die down to the bulb but the same leaves resume growth and form new blades the next one or more seasons. The occurrence of this manner of leaf growth in *Crinum Tinneanum, C. heterostylum* and *C. angolense*, and probably in *C. Baumii*, associated with biflabellate leaf arrangement, indicates that these species should be transferred to Ammocharis. The same peculiar feature of growth has been observed in some species of Crinum (subgenus Stenaster), but in these cases the spiral leaf arrangement, sheathing leaf bases and flower characters distinguish them readily from Ammocharis.

Graft Blight of Lilac

AN interesting case of delayed incompatibility between stock and scion of a graft union is described by C. H. Cadman in the *Gardeners' Chronicle* of January 13. Lilac buds upon privet stocks make good growth in the first season, but the foliage becomes rolled and mottled with yellow in the second year of joint growth. Leaves fall from the plant prematurely in subsequent seasons, and the ultimate result is a misshapen bush with thin, spindly shoots. The paper also reviews work by Chester, of the Arnold Arboretum, which shows that the trouble is non-pathogenic, and due solely to the incompatibility between stock and scion of the graft union. Use of common *Syringa vulgaris* for a stock, or burying the Syringa-privet union so that the scion can ultimately form its own roots, are suggested as control measures. It is also possible to propagate the common varieties of lilac by cuttings or layers, though a longer time is necessary to produce plants of saleable size by these methods.

Origin of Lake Toba, North Sumatra

THE history of Lake Toba provides one of the most convincing examples of a genetic connexion between tectonic and volcanic forces. In *De Ingenieur in Ned.-Indië* (4, No. 9, 126–140; Sept. 1939) van Bemmelen discusses the geological and volcanic evolution of the region and shows that the arching-up of a mountain range can, at least in part, result from the rise of magma or migma. The Toba cauldron is situated on the crest of a tumour-like culmination of the Barisan mountain range; it has an area of about 2,000 km.^{2} and a volume of 1,000–2,000 km.^{3}. On the top of the 'tumour' fissure eruptions occurred during the late Pleistocene, with a main paroxysmal phase of acid tuffs, followed by domes and outflows of acid lavas. The tuffs covered an area of 20,000–30,000 km.^{2} in Sumatra and extended to Malaya, where the thickness is still 5–20 ft. The volume of the tuffs is of the same order as that of the cauldron itself, which came into existence during or directly after the main outburst. The cauldron is therefore regarded as a 'super-caldera'. Van Bemmelen considers that a migmatitic batholith rose from the depths until it nearly reached the surface, arching up its cover and finally blowing out the gas-laden contents of its upper part through fissures in the roof. The paper is well illustrated and contains some interesting speculations on the origin of 'Pacific' magmas.

Heat Flow in the Earth's Crust

A. E. BENFIELD (*Proc. Roy. Soc.*, A, 173, 428; 1939) has investigated the outward flow of heat in the earth at a number of points in England by investigating the thermal conductivities of rock specimens taken from boreholes and using a knowledge of the temperature distribution in the same holes. The thermal conductivities were found by placing a carefully prepared rock slice between the ends of a divided brass bar in which heat was flowing; the thermal contact at the interfaces was eliminated by comparing results on specimens of different thickness. The conductivities found range from 0·017 C.G.S. (rock salt) to 0·0014 (shale), and the heat flows calculated vary between 0·7 and $1·5 \times 10^{-6}$ cal. per sec. per cm.^{2}. In the deep bores there was evidence of temperature disturbances consistent with the presence of an ice sheet on the surface up to 9,000 years ago. This necessitates a correction which brings the mean equilibrium heat flow up to $1·4 \times 10^{-6}$ cal. per sec. per cm.^{2}. E. C. Bullard (*Proc. Roy. Soc.*, A, 173, 450; 1939) has made similar conductivity measurements on rocks from deep bores on the Witwatersrand, and L. J. Krige (*ibid.*, 474) has made careful temperature measurements in these bores. The mean heat flow found is $1·2 \times 10^{-6}$ cal. per sec. per cm.^{2}. Both this value and Benfield's similar value in England are lower than those formerly estimated. It appears that there cannot be molten rock under England at a less depth than 20–30 km., while in the South African case, the layer of radioactive granite cannot be thicker than 12 km., and it is probably underlain by an intermediate layer as indicated by certain seismological observations.

Sun's Speed of Galactic Rotation

G. L. CAMM has published an important paper (*Mon. Not. Roy. Astro. Soc.*, 100, 1; November 1939) which leads to a much higher value for the velocity of the sun's galactic rotation than that generally accepted. The method adopted is to find the greatest difference between the angular speeds of rotation of the sun and of other objects in the galaxy, preferably those at great distances from the galactic axis, because their angular speeds would be small. Obviously a lower limit to the angular, and hence to the linear, speed of the sun can be determined in this way. Twenty-six globular clusters were divided into three groups, and it was found that the outer group, ranging from 12,000 to 38,000 parsecs from the galactic axis, appeared to be rotating as a rigid body—a view very difficult to sustain on dynamical grounds. Camm adopts the more reasonable hypothesis that the six clusters forming this group constitute a non-rotating frame, and their apparent motion is really caused by the opposite rotation of the sun. As an apparent angular velocity of — 410 ± 50 km./sec. per 10,000 parsecs for the outer clusters was found, the speed of rotation of the sun is 410 ± 50 km./sec. If it is assumed that the outer clusters are rotating, the absolute linear speed of the sun will exceed 410 km./sec. The other groups ranged from 10,000 to 6,000 parsecs and from 4,000 parsecs to the galactic axis, and it was found that the clusters have a differential motion; quantitative agreement exists between this motion and that of other types of objects. This, with other established facts, helps to confirm Lindblad's theory of sub-systems within the galaxy, each with its own speed of rotation.

THE SUTTON HOO SHIP-BURIAL

THE outbreak of war followed so closely on the gift to the nation of the antiquities from the Saxon ship-burial at Sutton Hoo, Suffolk, by the owner, Mrs. E. M. Pretty, which was announced on August 23, 1939, that there had been little opportunity for detailed examination of most of the objects, nor is any further occasion likely to arise while they are stored against damage. In these circumstances even the partial account to which the current issue of the official publication of the British Museum (Bloomsbury) (*Brit. Mus. Quart.*, 13, 4; 1939) is devoted affords information which will be welcome to archæologists and others, pending further study. A general account of the circumstances and character of the discovery and a description of the gold ornaments by Mr. T. D. Kendrick is followed by notes on the silver by Mr. Ernst Kitzinger, the coins by Mr. Derek Allen and other finds by Mr. T. D. Kendrick, who adds some reflections on the relation of the find to Anglo-Saxon archæology.

Mr. Kendrick points out that while some of the more important objects had been confided to the Museum as excavated, yet many of the notable objects, as, for example, the shield-boss and shield fittings, the helmet and sword have not yet been examined, and only hastily made record-photographs have been available for study.

It will be remembered that the barrow in which this ship was found was the largest of a group of twelve. The form of the ship, as traced, is more of the type of the fourth century type Nydam ship at Kiel than of the type of the Viking ships. The funeral deposit lay amidships under a collapsed wooden shelter in the form of a house with high-pitched roof, and constituted the richest series of grave goods ever found in England.

The richness and rarity of the finds is established by a brief description of their arrangement within the burial chamber measuring about 17 feet long by 8 feet wide. They were disposed H-wise, the horizontal bar corresponding with the keel of the boat and the uprights consisting of accumulations of offerings at the ends of the funeral chamber. At the west end was a standing bowl of bronze with drop handles and in this was a bronze hanging-bowl with elaborate enamelled ornaments, itself containing a wooden object with jewelled mounts that is probably a small stringed musical instrument, and other objects. By these bowls were heads of iron spears and augons, an ironbound wooden bucket, a huge lavishly decorated shield-boss and gilt shield-mounts, a gilt object believed to be a gaming board and among other objects an enormous ceremonial whetstone. Moving eastward, there was found the group of ornamental silver bowls and silver spoons, the remains of a magnificent helmet, the sword with a jewelled hilt of gold and the prodigious array of jewelled gold ornaments, sword harness and the outer trappings of a costly attire including the purse and its contents—gold coins and two ingots. Beyond these jewels were the remains of silver-mounted drinking horns, the great Anastasius and fluted silver dishes and a remarkable collection of miscellaneous objects.

Although the grave furniture was that of a man, there were neither vestiges of the buried body nor the ashes of cremation. Further, there was no single personal ornament of the deceased. Whatever may be the explanation, whether the barrow be cenotaph or grave, it is indubitably the monument of a pagan or semi-pagan royal personage possessed of huge wealth, who on the evidence of coins in his purse died before the first half of the seventh century. He may have been, it is suggested, Redwald, King of East Anglia, Bretwalda of England in 616 who died probably in 625.

The Gold Ornaments. In the fittings of the sword harness and outer apparel of their royal owner, all the pieces are contemporary and the work of one school, possibly of one man—one of the greatest of the many goldsmiths who worked in the cloisonné technique from the latter half of the fifth century onward. The most impressive single object is the massive gold buckle adorned in interlacing ornament and riello inlay, while next in importance comes the purse with its gold frame jewelled with garnets and mosaic glass and enriched with filigree bindings, its flanges, clasp and mountings ornamented in cloisonné and champlevé technique, while a number of minor ornaments are jewelled in garnets only.

The Silver. The outstanding find is the huge dish 27 inches in diameter, with a decoration of mixed ornamental designs. Byzantine control stamps, on which the monogram is of Anastasius, show it to be the work of a silversmith in the period A.D. 491–518. As a whole the silver objects are inferior as works of art to the gold. They belong to a decadent period of Mediterranean art, but within their own class they are important archæological documents. The large dish and the spoons throw new light on early Byzantine metal industry, and the smaller bowls appear to represent the art of certain semi-barbaric border regions of the Byzantine world which yet remain to be more clearly defined.

The Coins. The forty gold coins and two gold ingots found in the purse are the most inartistic objects in the whole burial, but nevertheless are of great importance, for it is on their evidence primarily that the dating of the burial must rest. They are of the denomination of tremissis or third of a solidus, and were all struck at Merovingian mints within or on the borders of France. Of none of the Sutton Hoo coins can it be said definitely that they were struck by a particular king, nor is any one of the moneyers known from historical sources. A rough dating is not before A.D. 600 nor likely to be before 640 or even 670.

Other Finds. Though intrinsically not the most valuable, the great ceremonial whetstone is archæologically the most amazing. Originally it was about 2 ft. long, square in section, the extremities adorned on each face with bearded masks, the stone ends in lobed bosses coloured red and enclosed in a bronze fitting with an empty and apparently useless cup-shaped terminal. Nothing like this stone exists anywhere else. Of equal importance archæologically is the bronze hanging bowl, with a mount from the centre of the interior floor consisting of an oddity in the form of a substantial bronze fish, perched on a rod rising from a circular base, enamelled in the same style as the borders of the exterior mounts.

Sutton Hoo and Anglo-Saxon Archæology. The salient fact of the Sutton Hoo discovery is that, taken as a whole, it is a revelation of a new Pagan Saxon art and archæology in England. It is both unfamiliar and startling. It is more than a pale reflection of the Jutish culture in Kent; it is the independent Golden Age in East Anglia confirming the historical fact of a dawning political ascendancy. Further, it will not be wise henceforth to debate the origins of our Christian art without paying respectful attention to this new evidence from Suffolk.

MINERAL RESOURCES

BY PROF. R. N. RUDMOSE BROWN

IT has been said, with a considerable measure of truth, that one of the decisive factors in war is the accessibility of either side to essential minerals. These include in addition to iron, as the basis of steel, various less widely spread minerals such as the ores of nickel, manganese, titanium, tungsten, etc., and also the ores of copper, zinc, lead, aluminium, etc., and of course coal and above all mineral oil. The statistical summary for the years 1936–38 afforded by this issue of an annual publication* is specially valuable in giving, for most metals, the amount of the ores produced in each territory of the British Empire and also, in many cases, the metal content of the ore.

The import and export for each country, including for some materials not only the crude materials but also the principal derivatives and semi-manufactured materials, are given. Unfortunately, for some important materials detailed figures are not available for all countries in 1938. To take first iron-ore, the world's production in 1938 was 165,000,000 long tons, of which 21,520,000 tons were from the British Empire and 28,700,000 tons from the United States. The other large producers were France with 33,000,000 tons, the U.S.S.R. with 27,000,000 tons and Sweden with 13,700,000 tons. Germany, Austria, Czechoslovakia and Poland between them produced about 16,000,000 tons. Of the great producers only France, with 15,200,000 tons and Sweden with 12,500,000 tons, were great exporters, while of the importers Germany was far ahead of all other lands with 21,500,000 tons. The report does not indicate the sources of this huge import, but Sweden and France were the chief contributors. The United Kingdom imported only 5,100,000 tons of iron-ore: the rest was mainly home produced but a small quantity of pig iron was imported. In 1938 the United States led the world in steel production with 28,000,000 long tons, followed by Germany with 23,000,000 tons, the U.S.S.R. with 17,500,000 tons and the United Kingdom with 14,000,000 tons. With her imports of iron-ore and iron curtailed, the German steel figure must show a great reduction in current times.

Nickel is an essential constituent of certain kinds of steel. Of the total world production in 1938 over 84 per cent came from Canada, another 10 per cent from French New Caledonia, a few tons from the U.S.S.R. and none from Central Europe. The two greatest importers of nickel were the United Kingdom and Germany, the latter probably leading, though different figures disagree. These two countries between them took well over half the world's output. There is now no important source of nickel available to Germany. Chrome ore is more widely spread, but at least forty per cent of the world's output is in the Empire, with South Africa and Rhodesia producing most. Other considerable outputs are in Turkey, Greece, Yugoslavia, Cuba, the Philippine Islands and New Caledonia. Germany used to be the greatest importer of this ore in Europe, producing none herself. Manganese ore is widely found. The Empire has about thirty per cent of the total production and though Germany has none, the U.S.S.R. has a great production and in recent years exported much.

Molybdenum ores are mainly in the United States, but Norway has large resources. Tin and cobalt ores are now almost inaccessible to Germany. One third of the output of lead-ore is from the British Empire, but some is still accessible to Germany from her own lands, the U.S.S.R. and Yugoslavia. Bauxite for aluminium can be obtained from Hungary and Yugoslavia, but supplies will be short.

Tungsten ores are not found abundantly in the Empire outside Burma, nor are there any considerable amounts in Europe outside Portugal. For several years Germany has been a large importer. Copper is another important metal of which the Empire produces about a third of the world's output, and the United States, Chile and the U.S.S.R. much of the remainder. Germany, producing little, used to be a great importer and still has access to Yugoslav copper ore.

Lastly, the position in regard to mineral oil may be noted, without going into details of quality and by-products. In this mineral the Empire is poorly endowed. In 1938 the Empire produced less than three per cent of the world's crude petroleum, the only lands producing a notable amount being Trinidad, the Bahrein Islands and Burma, and none of these produced one per cent of the world's total. The largest producers were the United States with 60 per cent, the U.S.S.R. and Venezuela, each with about 10 per cent of the world's total. Other considerable but much lower producers were Iran (3·8 per cent), Netherlands East Indies (2·7 per cent) and Rumania (2·4 per cent). Outside Rumania there was no noteworthy production in Central Europe: the Polish and Czechoslovak output were quite inconsiderable. The U.S.S.R. was a great exporter, by sea, of petroleum and allied products, but this trade she shared with all the large producers as well as Rumania. Thus even if the United Kingdom has ample sources of mineral oil within reach, it can scarcely be said that Germany is deprived of possible sources of import. There are, of course, problems of transport that may modify the position.

FACSIMILE TRANSMISSION

AN instructive paper, by G. Herrick, describing the progress in the United States of facsimile transmission, that is, the transmission of the printed page, drawings, photographs, documents and original messages by radio or wire telegraphy, appears in the *Electrical Review* of January 19. Certain electrical problems, more commercial than technical, have yet to be solved, and further development makes it necessary to use the best type of paper for recording purposes. Recently when President Roosevelt went to Canadian waters on a fishing trip, on board the U.S. Cruiser *Tuscaloosa*, he received a total of about 50,000 words of news on a facsimile receiver in his office-cabin, while the ship's officers received the same news on a duplicate receiver in the vessel's office.

The information transmitted was gathered by Trans-Radio News, set in type by the Koppel Printing Co. in New York, and broadcast from Cartaret, N.J., by the Finch system of transmission over the regular 780 kc. used by the station WOR of the Mutual Broadcasting Co. The transmissions were received in the afternoon in the *Tuscaloosa*, which reached a maximum distance of 650 miles from the transmitter. As the ship returned and neared New York, the smaller transmitter at the Finch Telecommunications Laboratories in Broadway, New York, took over transmission. For the transmission, alternating current at 110 volts and 60 cycles was used to energize both the transmitter and receiver. One of the difficulties to be overcome in the development of facsimile transmission is the fact that the power stations in different States often vary in frequency.

At present three systems of facsimile transmission of printed material and pictures are being developed. The R.C.A. system is controlled by the Radio Corporation of America and uses what is called 'percussion' recording through varying electrical impulses, which record lines on any grade of paper through the medium of a carbon sheet. The drawback is that it operates at only about three feet an hour.

The system controlled by Finch Telecommunication Laboratories records on special paper that is basically black and coated with an 'eggshell' surface. Across this an electric stylus travels, being regulated by impulses received at standard radio frequencies, or over a telegraph or telephone wire. The stylus draws a hundred lines to the inch and, by oxidizing the surface coating to a greater or lesser degree, records a variety of shades from grey to black.

The system of J. V. L. Hogan, consulting engineer of New York, was used with interesting results at the Toronto Fair by the *Globe-Mail* of that city. This method also employs the stylus principle of recording. Instead of oxidizing a specially coated paper, a series of points that are in contact with specially sensitized paper in rolls delivers varying electrical impulses to the paper and develops the required type of picture as the paper unrolls in the receiver. This system is extremely clear and can record very minute details, such as a photograph of a lace tablecloth or type down to 6-point. All the three differing systems require the material to be transmitted to be placed on a revolving drum, so that it is scanned by a point of light with which is associated a photo-electric tube that reacts to the reflections of light from light and dark substances, varying the impulses sent out.

In the United States, development of this kind of transmission has been delayed by the public and technical interest taken in television. To-day, with television making satisfactory progress, facsimile transmission is being developed rapidly. What the public want is low-cost synchronizers which are both efficient and do not slow down transmission. Some of the synchronizers in use necessitate low speed. The transmissions to the *Tuscaloosa*, for example, were received at three feet an hour.

Photographs both by radio and wire are being sent across the Atlantic at the present time. As an indication of future possibilities, consider the dissemination of news from one city to another by transmitting entire printed pages with illustrations, which would be multiplied by photo-offset printing, and could be sold in the streets within two hours after being sent. This plan envisages the use of wired rather than wireless transmission; technicians engaged in facsimile development suggest that their experiments have indicated that wired facsimile may be less certain than wireless, except in certain sections.

Unlike the television receiver, facsimile apparatus can be built at low cost because it is comparatively simple. The cheapest television sets in the United States cost about £39, but it is believed that a standard facsimile receiver could be constructed to retail at £10.

The Finch organization has recently brought out mobile facsimile transmitters and receivers. Several police motor-cars in Bergen County, New Jersey, just across the Hudson River from New York City, have been equipped with facsimile two-way units that can send and receive alternately. A New York newspaper is experimenting with a motor-car into which is built transmitter, receiver and a dark room. It has a tiny writing space and typewriter for the news man.

The Finch Company has developed a method of utilizing any telephone; strangely enough, the method has been approved by the telephone company, which has rigorous rules against tampering with its lines or equipment. The unit is an inductive coupling and cable. With one end of the cable attached to the transmitting and receiving unit in the motor-car or special truck, the other end of the cable is carried from the kerb into the nearest public or other telephone. The user then calls the telephone operator and says, "Do not interrupt, this wire is being used for a facsimile transmission". The use is thereafter charged at the ordinary telephone rate. During the transmission of news and pictures in this way, it is not necessary to use the telephone, as the office of reception can transmit messages of instruction back to the truck transmitter by writing and having them scanned on its own transmitting drum.

Similar testing of facsimile is being done by the U.S. Army, and the Navy is understood to be increasingly interested in possible use of facsimile for intercommunication between naval ships and messages to and from bases.

PROPAGATION OF RADIO WAVES ALONG THE EARTH

THE mode of propagation of electric waves along the surface of the earth has been investigated theoretically since the earliest days of practical radio communication, and a paper by A. Sommerfeld published in 1909 has since become a classical treatise on this subject. After a period during which attention was mainly confined to the study of wave propagation through the ionosphere, the inception of broadcasting and the practical application of ultra-short waves have caused renewed interest in the problem of propagation along the ground.

Two papers having a direct bearing on this subject have recently been issued by the Institution of Electrical Engineers, and would, in normal circumstances, have been read before a meeting of the Wireless Section on January 3. The first, by Dr. J. S. McPetrie and Miss A. C. Stickland, is entitled "Reflection Curves and Propagation Characteristics of Radio Waves along the Earth's Surface"; it deals with the evaluation of the reflection coefficient of the earth's surface, and then with the application of this knowledge to the study of propagation along the earth. A collection of curves given in this and an earlier paper enables the reflection coefficient for radio waves of any frequency and state of polarization to be determined for any angle of incidence and for various values of electrical constants of the earth.

It is pointed out that the ray theory, on which the reflection from a surface is assumed to be equal to the radiation from an image of the transmitting aerial, is not applicable at grazing incidence unless the heights of the transmitting and receiving aerials are comparable with the wave-length. From an analysis given by K. A. Norton, however, it is deduced that, when the ray theory does not apply, the field at the receiver is equal in most practical cases to the vector addition of two fields; the first is the field given by the simple ray theory while the second, which is independent of the heights of transmitter and receiver, corresponds to the surface wave first postulated by Sommerfeld for vertically polarized waves. The ratio of the magnitudes of the surface wave to the image fields is much less for horizontally than for vertically polarized waves, so that the ray theory is applicable over a wider range of angle of incidence in the former case. As the surface wave is independent of height, this results in the well-known experimental fact that the vertical field from a low transmitting aerial increases in magnitude with height at a much smaller rate than the horizontally polarized field.

The second paper, by Dr. J. S. McPetrie and Mr. J. A. Saxton, describes the results of an experimental investigation of the characteristics within optical range of the propagation overland of radio waves of length 2 and 3 metres. Measurements of the field strength received at various distances from the transmitter confirm the theoretical deduction that, provided the heights of both transmitting and receiving aerials are comparable with the wave-length, the propagation at grazing incidence is the same for both horizontally and vertically polarized waves. In either case, the field strength is proportional to the product of the heights of the transmitter and receiver, and inversely proportional to the square of the distance between them. It was found that, within the optical range of the transmitter, the propagation characteristics corresponded to the condition of a plane rather than a spherical earth, although the varying contours of the path of transmission produced a marked effect on the received field strength. Over a town area, the ratio of the measured to the theoretical field strength was less on a wave-length of 2 metres than on 3 metres.

CAVE FAUNAS

THE specialized cave faunas of the world have been investigated extensively during the last fifty years, and to this prolific literature is now added the results of exploration in the numerous caves of Belgium. Dr. R. Leruth contributes "La Biologie du Domaine Souterrain et la Faune Cavernicole de la Belgique" (Mém. 87. Musée Royal d'histoire naturelle de Belgique, 1939), and in the same series, Mém. 88 by Dr. C. R. Boettger is entitled "Die Subterrane Molluskenfauna Belgiens".

The vast grottoes near Han-sur-Lesse furnished much of the material, although forty-eight subterranean regions were explored. The collections were submitted to specialists for identification. A general section deals with the ecological and geological conditions affecting the Belgian cave faunas, and Dr. Leruth classifies the inhabitants as permanent, temporary or accidental cave-dwellers. The first are completely adapted to their mode of life, the second can live either within or without underground areas, and the third are ill-adapted to cave life and are incapable of breeding there. There are also parasites and scavengers. The terrestrial fauna is poor in species, but the aquatic fauna is relatively rich. Of approximately six hundred species, one genus and sixteen species are new. Bats, mice and rats are the chief mammals, while badgers and foxes penetrate into the smaller caverns. Neither fishes nor amphibia are recorded. Among invertebrates, flatworms, roundworms and ringed worms, arthropods of all kinds and in large numbers, and some molluscs were found.

Dr. Boettger describes the collections of Dr. Leruth and Prof. Séverin. Pisidium is the only lamellibranch genus. Among prosobranchs there are several members of the Hydrobiidæ. Pulmonates are common, especially as the faunas of crevices and underground water channels are included. A blind land snail, *Caecilioides acicula*, and the freshwater prosobranch, *Avenionia bourguignati*, are true cave forms, the latter being a French species recorded for the first time in Belgium.

MINE RESCUE TELEPHONE

Mr. R. C. WOODS, of the Ericsson Telephones, Ltd., London, communicates a description of a mine rescue telephone to the *Ericsson Review* of 1939 (No. 2). The Coal Mines Regulations require owners of mines, to which the regulations apply, to make definite provision for rescue work in mines after an explosion, fire or other accident. Telephone communication between the rescue brigade and its base is of great importance. Ericsson Telephones, Ltd., in collaboration with the Mines Department Testing Station, have constructed a mine rescue telephone which was officially tested last year, after which the production was immediately undertaken.

When a rescue corps is called to a mine, a base is immediately established in fresh air but as near as possible to the zone where the air is so foul as to be unbreathable. As the team of from eight to five men will be wearing breathing apparatus, speech is impracticable and communication has to be established by other means. Uniform codes of signals are prescribed, one for use between members of a brigade, for which each man carries a bulb hooter, and one for electric signalling. While the existing mine telephone system may provide for the telephone communication between the rescue corps and the base, it cannot be depended on and it would rarely prove convenient, speech not being practicable owing to the breathing apparatus, both of which are vital factors in such an apparatus, which only comes into use in severe conditions.

The mine rescue apparatus constructed by Ericsson's consists of two units, a base station and an advance station, connected continuously by a light but tough cable. In the constructional features of the design, particular attention has been paid to strength and low weight.

Signals in both directions are effected by a buzzer, using a special code. The note is distinct and penetrating, the high frequency avoiding any chance of confusion with other noises. In addition, the base party can speak to the advance party, both speech and signals being received on the loud-speaker at the advance station unit. After much consideration it was decided to limit to key signals only communications from the advanced party. If both-way speech were provided, the additional equipment would appreciably reduce the mobility of the advance party.

The base station unit is about 24 cm. square with a depth of 16 cm. On the front of it there is fitted a sensitive transmitter, a small loud-speaking receiver and a high-frequency buzzer. When the keys are in their normal position, the loud-speaking receiver is connected directly to the trailing cable and hence to the advance station unit. Any signal sent out by the advance party is thus immediately reproduced by this receiver. The batteries are of the ordinary cycle lamp type so that replacements are readily obtainable. Battery voltages are 6 and 3 volts respectively for the use of the base and advance party units.

Safe operation in dangerous atmospheres is a feature of this system. If during rescue operations it is desired to extend beyond the first cable length, a further advance party instrument can be connected by a simple plug and the circuit transferred from the first to the second unit.

SEVENTY YEARS AGO

Nature, vol. 1, February 10, 1870

The Royal Commission on Science

"The Council of the British Association for the Advancement of Science was received on Friday last by Earl de Grey, Lord President of the Council, as a deputation to urge on the Government the issuing of a Royal Commission to inquire into the state of Science in England.

"The main points for a Royal Commission to throw light upon are these. First, is it right that science should be aided by the State ? Secondly, is the aid now given exactly what is needed—neither too much nor too little ? Thirdly, the degree and direction in which science should become a State business having been settled, what will be the best organisation for the purpose ? Not one of these points has ever yet been thoroughly considered in England."

Microscopical Investigation of Meteorites

Prof. N. S. Maskelyne, of the British Museum, provided a full abstract of his recent paper on this subject presented to the Royal Society. Transparent sections of small fragments cut from meteorites were studied under the microscope. They showed that "a meteorite has passed through changes and that it has had a history of which some of the facts are written in legible characters on the meteorite itself and, one finds, that it is not difficult roughly to classify meteorites according to the variety of their structure. One also recognises constantly recurring minerals ; but the method affords no means of determining what these are". The chief use of the microscope was as a means of sorting out the various minerals from "the bruised débris of a part of the meteorite", investigating each by the goniometer and by analysis, "and finally returning to the section to identify the actual minerals present".

The Work of the Sea

In an article by C. W. Whitaker, M. Quenault is quoted as concluding, with regard to the depression of the land : "One gathers from all these evidences, that the movement, since the eighth century, has been about two metres a century. If it continues at the same rate for ten centuries more, the peninsula of Cotentin will be an island and all the ports of La Manche will be destroyed. Some centuries later and Paris will be a seaport, waiting only to be submerged in a score of centuries. Thus in a period, less than half as long as that during which the pyramids of Egypt have braved the ravages of time. Paris itself—if it is not burned down during one of the revolutions of its inhabitants, as amiable and *spiritual* as they are inconsistent—Paris will probably be engulphed in the Atlantic, a master before whom the intractable Parisian must haul down his flag. Let him take warning !"

With reference to the "situation" at the Paris Observatory [see Nature of February 3, 1939, p. 198], the action "of the French Government has been of the promptest and M. Le Verrier is no longer Director. This step indicates very clearly—too clearly we fear—the strength of the case put before the Minister of Public Instruction. . . . The document was signed by Villarceau, Marié-Davy, Wolf and Loewy. . . .

It is to be sincerely hoped that M. Le Verrier may be able yet to do service to astronomy, in some other capacity, some position where his great talents alone will be called into play."

"A new office has been constituted under the Public Works Department and Mr. Douglas Galton, C.B., F.R.S., has been appointed to it with the title of Director of Works and Buildings. We may congratulate ourselves that our public building will be looked after by one so eminently qualified by his high scientific attainments and great experience in such matters."

M. Vérard de Sainte-Anne read a memoir before the Paris Academy of Sciences on a project for establishing communication between France and England. The author proposed the establishment of a railway bridge, either open or tubular, across the Straits of Dover.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Commissioned Ordnance Mechanical Engineers in the Indian Army Ordnance Corps—The Secretary, Military Department, India Office, Whitehall, S.W.1 (quoting 'O.M.E. Recruitment') (February 14).

Director for the British Institute in Milan—The British Council, 3 Hanover Street, W.1 (quoting 'Milan') (February 15).

Research Officer for Bacteriological work—The Secretary, Agricultural Research Council, 6a Dean's Yard, Westminster, S.W.1 (March 31).

Radio Engineers by the Royal Army Ordnance Corps—The Under-Secretary of State (A.G.9), War Office, Hobart House, Grosvenor Place, S.W.1.

Mechanical and Automobile Engineers by the Royal Army Ordnance Corps—The Under-Secretary of State (A.G.9), War Office, Hobart House, Grosvenor Place, S.W.1.

Engineer and Ship Surveyor for the Department of the Surveyor-General of Ships, Straits Settlements—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9066).

Temporary Forecasters, Grade II (Male), in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

CIVILIZATION AND THE RIGHTS OF MAN

MUCH has been said and written recently on the causes of the present conflict between Germany and the Allies and the conditions of peace, but most of it has been from the point of view of national expediency and little from that of the history of civilization or the future of mankind. In his two latest books—"The Fate of *Homo sapiens*" and "The New World Order"—Mr. H. G. Wells takes an eagle-eyed view of the world of man, as he did in his "Outline of History", and brings his critical mind to bear upon what he sees. With a few other students of history he realizes that the scientific method of inquiry can be profitably applied to political and social problems, as it is to other aspects of biological development. In the struggle for existence of all forms of life, many factors are involved; and the aim of scientific investigation is to discover their nature and influence. The history of civilization shows that the chief causes of war have been migratory movements—represented in modern times by access to natural resources and the claim for *Lebensraum*—aggressive nationalism, racial lust and religious hatred.

In the natural instincts which have led to struggles between groups of peoples, mankind is the same as it was at the beginning of civilization six thousand years ago. There has been great increase of knowledge but not a corresponding increase of wisdom in the use of it. If an individual or a nation has the will to assert a claim by force, he can acquire in an open market whatever power he is prepared to pay for and use. In a civilized community, citizens protect themselves from such dangerous disturbers of the peace by means of a police force; but there is no similar force to prevent breaches of the world's order by truculent nations, and no international court whose judgments upon disputes are accepted as final.

If the civilized world is to survive, the hour has come when measures will have to be devised to control the "gangster" element in human nature, whenever or wherever it manifests itself. Authority to exercise such power will come only when nations believe that it is in their own interest to combine for the common good of the whole community of mankind. How this end can be attained, and the changes which will have to be made in social and political structures in order to achieve it, signify reconstruction of existing systems in a manner which may rightly be described as revolutionary. The aim of such a revolution is not, however, to readjust class relationships, but to create a world commonwealth of free peoples conscious of their responsibilities one to another, and accepting the principle of "Live and let live" rather than that of "Lie and let lie", which is often an excuse for political diplomacy.

This is the type of revolution which Mr. Wells foresees, if civilization is to be saved from self-destruction. He urges that "It is the system of nationalistic individualism and unco-ordinated enterprise that is the world's disease"; and that the old foundations of the system have proved unable to support the ponderous structure which has been built upon them. To strengthen one part by political balance of power or alliances makes other parts of the structure relatively weaker, with the result that the stability of the whole suffers. Mr. Wells has, therefore, no sympathy with the movement for the federation of a number of European States, unless it is deliberately made the basis of a system designed ultimately to comprehend all the peoples of the world.

There is nothing new in the spirit of this intention. The philosophy of the Stoics included the principle of the brotherhood of man and the merging of all nationalities in a cosmopolitan citizenship. Christianity adopted the same ethical doctrine, and still pursues it; yet neither in economic nor in political spheres are national policies or actions determined by it. After nearly two thousand years of teaching peace on earth, good will towards men, this principle of all systems of ethics does not enter into the field of practical politics of Christian nations any more than it does in other communities. It may be that a world commonwealth of nations is just as far off as a world fellowship of religious faiths, but that does not make the ideal less worthy of effort to attain it. The mines and torpedoes which lie in the track of civilization at the present time make it more necessary now than ever it was for navigators to be guided by a single light, instead of each ship of State, or convoy, following a course which must cross the tracks of others and lead to collisions.

Though, in the past, war has played a part in the formation of certain groups, it represents only one phase in the development of civilization. It is true that civilization has developed through individual peoples, as, historically speaking, mankind has been organized on that basis, but we, as heirs of the ages—to use a trite but expressive phrase in this connexion—are not interested in the survival of these peoples, except in so far as they have contributed to the general advancement of the human race. The trend of cultural achievement in the advancement of mankind has been to operate through larger and larger unities—tribe, people, nation, confederacy—eliminating war and the struggle for existence as physical facts, and relying more and more on the struggle for existence between ideas.

It is towards such a world commonwealth, in which each nation can be free to follow its own course of cultural development, that Mr. Wells would direct civilized thought. It may be held that this conception represents merely a reversion to primitive social structures; but the difference is in the extent of outlook. Whereas, in the primitive form, the sense of responsibility embraces the members of the same blood-kin only, or those of the local group within which the members are more or less intimately acquainted, in a modern society it may reach out to embrace all members of a great nation, and possibly, when conflicting creeds and ideals agree to sink their differences, it may extend to all men of good will, to whom the dignity of man as an individual entity transcends racial and political boundaries.

When, if ever, this comes to pass, it will be possible to gauge how far mankind has advanced along the road of ethical as well as material progress. To many, the way seems long to go. The urge of nationalism and its ideals, combined with belief in might as the sole arbiter of right, has diverted the thoughts of peoples away from the main stream of human progress into narrower channels in which rocks and rapids threaten at every turn to shipwreck all that is best in civilization.

In what is conceived to be the highest type of civilization to-day, certain ethical and humane sentiments, such as those of truth and righteousness, justice and mercy, and sympathy with the weak and suffering, are possessed and practised by a greater number of the community than ever before. These high attributes of human nature have survived the ages of violence, cruelty and rapine which have disgraced European history, and by which the recrudescence in our own times will be remembered. In spite of these degrading influences, there has been an increase in the true, the humane and the just, and the standards of conduct towards others have become ethically higher, until now no people or nation which reverts to such methods can claim to be in the van of modern civilization. In so far as the present conflict is one of ideals, it may fairly be said that those of the Allies represent a far higher ethical standard than exists at present in Germany.

Freedom of thought and speech, belief and investigation, subject only to the recognition of the same liberty on the part of others, is threatened by the new tyrannies which, through their aggressive militarism and economic nationalism run mad, seek to reduce the citizen to a soulless unit and a condition of moral and intellectual servitude. The existence of economic antagonism and military rivalries among nations is as grave a danger to scientific thought and investigation, upon which so many material achievements are based, as it is to the general progress of civilized life. Science must, therefore, stand for high human values, as against slavery of the spirit of man, if civilization is to be preserved from the dangers which now threaten it.

There are certain fundamental human rights the recognition of which would do much to promote a sense of common interest among the peoples of the world. Mr. Wells gives the first draft of such a Declaration of the Rights of Man in his "New World Order"; and the *Daily Herald* is submitting it to free and wide discussion with the view of constructing a new charter to represent man's just claims in a modern society. The intention is eventually to produce a Declaration which will represent world-wide opinion, and will crystallize the thoughts of men and women of all ranks and of all races who believe in the essential greatness of mankind. It is hoped that such a Declaration at the present epoch may have valuable consequences in shaping the structure of human society to the benefit of mankind.

Representatives of science are invited, with those interested in other fields of progressive life, to assist in making the final form of the Declaration a worthy and enduring statement of human needs. The time has come for the assertion of the rights of scientific and other intellectual workers in modern life, in view of the conditions of cruelty and suppression to which their work is now subject in some countries. Such a Declaration would insist that creative ideas are the essence of progressive thought and achievement in science, as in art and literature; and that to make them subversive to the principles of any social doctrine or political system is to restrain the expansion of the human mind and its means of expression. Research can be organized and team-work be profitably applied to solve particular problems, but the true heart of science is in original independent thought; and this can neither be created nor regimented by political authority.

It has been suggested that a charter should be framed embodying these and other principles of liberty of thought, and freedom from the frustration by authority, which have long been assumed to be characteristic of scientific activity. Little encouragement has been given to this idea in scientific circles, otherwise the Society for the Protection of Science and Learning, or the British Association's Division for Social and International Relations of Science, would no doubt have produced such a charter. The world of science is international in its constitution and aims, and citizenship can be claimed in it by men and women of any race or nationality who will respect the principles implied in the pursuit of scientific truth and endeavour to contribute to the advancement of natural knowledge by following them. The Declaration of the Rights of Man which should emerge from the discussion organized by the *Daily Herald* will no doubt include these principles, among others which may be justly claimed by all the citizens of the modern world.

PROPERTIES OF MATTER IN BULK

Statistical Thermodynamics

A Version of Statistical Mechanics for Students of Physics and Chemistry. By Prof. R. H. Fowler and Dr. E. A. Guggenheim. Pp. x + 693. (Cambridge: At the University Press, 1939). 40*s.* net.

PROF. R. H. FOWLER, with the able assistance of Dr. E. A. Guggenheim, has produced a book which will serve in many respects as a third edition of his "Statistical Mechanics", but which does not supersede the former work entirely. The present book is written with rather a different aim in view. The first edition of "Statistical Mechanics" gives the impression that the author's interest was centred primarily on a new and elegant mathematical technique, the "method of steepest descents", which could be applied with profit to a very large number of physical problems. The second edition represents a transition stage, with more emphasis on the physical problems and less on the principles of statistical mechanics. In the present work the shift of emphasis is complete. It is a book, admittedly written from a mathematical point of view, about the properties of matter in bulk. Theorems of statistical mechanics and of thermodynamics are both used, as may be convenient, to discuss the problems under consideration; once the laws of thermodynamics and their connexion with statistical quantities have been derived, full use is made of them whenever it seems advantageous. It was this fact which suggested the title "Statistical Thermodynamics" given to the book.

In accordance with the utilitarian nature of the book, no discussion is given of the truth of the fundamental axioms of statistical mechanics; these are merely stated, and the reader is referred to recent books on the foundations, such as that by Tolman. Since, moreover, it is intended primarily for students of physical chemistry (or, may we say, chemical physics), the chapters which appeared in the old book about astrophysical and atmospheric problems are omitted.

After the general methods of statistical mechanics have been discussed, the book opens with a discussion of the specific heats of perfect gases, which has been brought thoroughly up to date. Chapters on crystals and on chemical equilibria follow, and then chapters on imperfect gases, liquids, and the theory of condensation. Solutions of electrolytes, adsorbed surface layers, elementary electron theory of metals, lattice imperfections and order-disorder in crystals, and dielectric and magnetic properties of matter in bulk are other subjects treated. There is also a chapter on chemical kinetics, which, although not a subject which can be included under the heading of the properties of matter in equilibrium, is nevertheless a field in which the methods of statistical mechanics have been applied extensively to calculate the number of molecules in the activated state.

A study of the book and in particular a comparison with Prof. Fowler's earlier treatise is interesting especially in reminding the reader of the subjects in this field which have received the most attention from theoretical physicists during the last four years. There are in particular the complexities of the problem of the liquid state, which resist as obstinately as ever all attempts to write down a partition function even for the simplest liquid. The authors give an account of the various more or less crude models which have been proposed to describe liquids, and they also develop the theory of Mayer, Born and others about condensation.

The recent discovery of the existence of alloys in which an ordered superlattice gradually disappears as the temperature is raised has provided an invigorating incentive to mathematical research on what are known as co-operative phenomena. By this term is meant the variation with temperature of the equilibrium state of a body in which the forces holding each molecule in some normal or ordered position depend on the number of its neighbours which are themselves in ordered positions. In a sense the fusion of a solid may be regarded as a co-operative phenomenon, but the order-disorder transition in alloys presents a problem which is much more amenable to mathematical treatment, because in an alloy each atom has the choice only of an ordered or a disordered position, instead of the infinite number of positions which are possible for a molecule in a liquid.

The earliest mathematical treatment of any phenomenon of this type is Weiss's theory of ferromagnetism and its disappearance above the Curie point; but the further development of the subject as a problem in statistical mechanics has been hindered by the difficulty of giving a satisfactory account, from the point of view of quantum mechanics, of the interaction between the elementary magnets. The difficulty arises partly from the fact that the elementary magnets, namely, the electrons, do not stay in the neighbourhood of definite lattice points but wander through the crystal. In alloys, on the other hand, in spite of the primitive state of our knowledge of metallic cohesion, it is a reasonable hypothesis that the simple assumption of a law of force between neighbours is a sufficient basis for a theoretical attack on the qualitative aspects of the problem. This, at any rate, is the point of view taken in the book under review, and a very full account is given of the various theoretical attempts to set up a partition function for the system, and to find out whether there should be a phase change at the transition point, or whether only the specific heat or even its first derivative is discontinuous.

The present reviewer welcomes the appearance for the first time of an account of the Wagner-Schottky theory of lattice defects in crystals in thermodynamical equilibrium. Apart from its interest in explaining ionic conduction in crystals, and the importance of the concept for the theory of chemical reactions in solids, the theory has a considerable didactic value. In teaching statistical mechanics to students, it is often advisable to put off the study of gases for as long as possible, because of the difficulty in evaluating the chemical constant, and hence the entropy of a gas, without a much deeper incursion into quantum mechanics than the average student can follow. Interstitial atoms or vacant lattice points in a crystal have many of the properties of a gas, but since one can count directly the number of ways in which they can be arranged, expressions for their entropy and free energy can be written down without any appeal to quantum mechanics at all. The present reviewer has found that the subject forms an excellent introduction to the study of chemical equilibria, in the further development of which there is a good deal that the average student has to take for granted.

Readers of Prof. Fowler's earlier books will not need to be assured of the thoroughness with which the work of revision has been done, or of the masterly and complete mathematical treatment of the physical problems which are discussed. Students approaching the subject without much mathematical knowledge will, we think, find it easier than in the previous books to discover the formulæ that they want and to understand the steps by which the formulæ are obtained. The book is written with the needs of practical workers in physics and chemistry in mind, and it is a remarkable achievement to produce a treatise so eminently useful without sacrificing mathematical rigour or completeness in any way.

N. F. MOTT.

PRINCIPLES AND PRACTICE OF EDUCATION

Knowledge and Character
By Dr. Maxwell Garnett. Pp. xii + 358. (Cambridge: At the University Press, 1939.) 18*s*. net.

DR. MAXWELL GARNETT in this book approaches the problems of moral education from the point of view of physiology and experimental psychology. Time was when recourse to scientific method would have meant that the author was committed to a materialistic and determinist interpretation of the mental and moral life. But that is no longer the case. Science has shed almost every trace of *a priori* dogmatism, and we find Dr. Garnett frankly advocating the hypothesis of interaction between mind and body as the most reasonable explanation of the facts. True, he raises a good many problems of a speculative order which the limits of his space do not permit him to discuss fully. He ranges in the course of his argument over the theory of knowledge and of being, touching also in highly suggestive ways on questions of religion and the ultimate aim of life. We find him speaking of what are strictly psycho-physical generalizations, such as the five formulated in the earlier chapters, and summarized collectively on p. 273, as though they were laws of *thought*; and a good deal of his physiological theory of neurograms, each of which corresponds with varying complexity to a concomitant mental process, is of the nature of highly inferential construction from data that are strictly psychological. Indeed the concept of correspondence which occurs very frequently in these pages seems to us to stand in need of a good deal of detailed explanation. It may well be questioned whether the method of explaining psychological facts by speculative physiological deductions from the very facts to be explained has sufficient logical validity.

An adequate criticism of the book would require a combination of expert knowledge in physiology, psychology and philosophy. The present reviewer can claim competence only in the last-mentioned of the three. In regard to the physiological sections he can but note how carefully documented is the evidence from the highest authorities such as Head and Sherrington. In psychology, Dr. Garnett naturally draws upon his own work in collaboration with Spearman. His mastery of the technicalities of factor analysis, and especially of the *g*-factor, in the mental outfit of the individual, is strikingly displayed in Chapter vii, and should prove most fruitful in the shaping of educational theory.

On the broader speculative issues handled in the last half of the volume, Dr. Garnett's views will doubtless cause some searchings of heart among philosophers. One of the points most open to question is his theory that the soul acts only through the will, and by way of selection and choice between alternative neurograms. It is a little difficult to understand the status of the soul, which seems to be of the nature of a pure ego, in itself unaffected by the development of character, and yet capable of functioning without any physiological correlate. Indeed, in one very interesting note, Dr. Garnett suggests the possibility of direct communion between souls, and again between the human soul and God. Such a relationship is presumably purely spiritual. "It is not inconceivable," he says (p. 162, note 1), "that another Soul—God perhaps—or other souls should communicate directly with our souls. In such a case it is possible to imagine that the other soul which communicates with mine does so directly, soul to soul, or indirectly by first causing excitement in my brain. Since, however, my own soul cannot create, but only re-inforce, excitement in my brain, it is not to be supposed that any other human soul has power to *create* excitement in my brain; but we may choose to suppose that God has it, and sometimes exercises it. It is, however, simpler, and therefore preferable, to suppose that all purely psychical communications proceed direct from soul to soul."

In another respect, the adoption of a strictly scientific approach leads Dr. Garnett to lay stress on the importance of psycho-physical generalizations in the training of moral character. As he rightly says, "it is the faith of every science that an unlimited number of phenomena can be comprehended in terms of a limited number of such propositions, principles, or 'laws'. The phenomena are explained as particular examples of the working of general 'laws'." (p. 8).

Now this method is certainly very fruitful when we are dealing with character and conduct on their lower and less complex levels. Then these general rules and laws of habitual behaviour come predominantly into play. But on the higher levels of thought and action, purposes and interests are increasingly unique and individual, defying reduction to any combination of generalities. It is to Dr. Garnett's credit that he frankly recognizes this limitation of scientific method in its application to education. He puts great stress on the development of personality in the individual, who is moved, in William James's phrase, by "partial purposes and private ends". This is all the more suggestive because of Dr. Garnett's frank adoption of the Christian hypothesis (Chapter xv) as making more sense of human experience than any other. Christian saints and teachers have always insisted that the element of self-love is ineradicable from human nature, even in the state of perfect consummation in communion with God. Spiritual growth consists in the passage from self-love, detached from love of God, to self-love in and through love of God. It is interesting to find repeated confirmation of this cardinal religious tenet in the physiological and psychological positions advocated by Dr. Garnett.

Enough has been said to show the wide range of interest in this volume. Dr. Garnett brings to his task long experience in educational administration, a wide knowledge of human affairs and a humanistic culture that is rare in a trained man of science. The result is a book that throws light both on educational principles and on their practical applications, as, for example, in the Spens Report, to which frequent reference is made throughout the volume. There is an excellent index.

W. G. DE BURGH.

SIR JAMES FRAZER'S NOTEBOOKS

The Native Races of America

A Copious Selection of Passages for the Study of Social Anthropology from the Manuscript Notebooks of Sir James George Frazer. Arranged and edited from the MSS. by Robert Angus Downie. (Anthologia Anthropologica.) Pp. x+352. (London: Percy Lund, Humphries and Co., Ltd., 1939.) 35*s*.

THE issue of the fourth and concluding volume of extracts from the notebooks of Sir James Frazer, edited by Mr. R. A. Downie, must inevitably provoke certain general reflections on the work as a whole. Among these, the first to emerge in the minds of all will be admiration for Sir James's genius, mingled with a profound amazement at the stupendous energy and industry which have extracted and digested the material apt to his purpose from so vast a literature as has been sampled in these four volumes. With a penetrating insight into the working of what might be termed the 'traditional' mind of primitive man, he has disentangled from an enormous body of recorded fact the significant threads in the evolutionary development of religious beliefs and emotional reactions in a vast variety of forms of the social environment. The task has demanded a logical grasp and a power of generalization which have been equalled by the lucidity and persuasive eloquence with which the argument has been presented to the world. The supplementary evidence contained in "Anthologia Anthropologica" is no less an integral part of the monument, which is Sir James Frazer's life work, than "The Golden Bough" or "Totemism". For its publication we are deeply indebted to Lady Frazer and the editor, to both of whom Sir James pays well-deserved and graceful tribute in a foreword.

It will be remembered that the principle upon which the contents of these volumes have been selected is that recent sources have been set aside, with a few exceptions, and only the older, less accessible and less known material has been included. Hence from the nature of the material, the extracts present a view of primitive man unsophisticated and as he was to be found in the remoter parts of the world between the sixteenth and latter parts of the nineteenth centuries, but more especially in the eighteenth and nineteenth centuries. The conditions in which he was observed by those writers from whom these extracts have been drawn have long passed away; and their record correspondingly is of enhanced significance for the anthropologist.

This consideration is of special application in estimating the value and interest of the extracts which deal with America. They are records, of which some were familiar to a past generation of anthropologists, but with the development of new methods and a new outlook in America, now receive less consideration than they deserve. Such are for example H. Rink and Hall on the Eskimo, and the valuable reports over a series of years of the Ethnographical Survey of Canada, unfortunately interred in the Annual Reports of the British Association. Here also is much of the early work of F. Boas on the Kwakiute of the north-west, of J. Teit on the Thompson Indians of British Columbia, and the valuable Reports of the Jesup North Pacific Expedition. It is, however, in its earliest records that the literature of indigenous America is at its best, and although "The Golden Bough" has drawn liberally on these sources, it has been possible to add much from Sahagun, Valdes, Herrera, and Ariaga on the extirpation of idolatry in Peru, and other early

Spanish writers who were in a position to obtain or give first-hand information on pre-conquest or early post-conquest peoples in Central or South America—material of which anthropologists, with the exception of those known specifically as 'Americanists', make too little use.

The records of American peoples, whether early or late, from which these extracts are taken, are of even greater interest than those relating to other parts of the world. Outside America, except for isolated instances, such as the Tasmanians, the people still exist, though their conditions of existence have suffered modification. In North America, excepting in the remote north-west and among the Eskimo, as Harlan I. Smith pointed out some years ago, it is becoming increasingly necessary to employ the methods of the archæologist in ethnographical investigation. The transfer of the Indians to reservations has sapped or destroyed their culture, except where special reasons, mostly economic, artificially prolong an attenuated existence. Recent ethnographical studies have had to depend upon the memories of a few rapidly disappearing elders among the tribesmen. Hence the value of even the scantiest record of earlier conditions.

A map of "Some Indian Tribes of North America" is included. It is too incomplete to be of much value as a guide to the text and is unworthy of the care which has been lavished on the production of this and the three earlier volumes.

The fifty-five notebooks containing the material, written in Sir James Frazer's own hand, and the product of more than fifty-two years of unremitting labour, from which the extracts appearing in the four volumes of "Anthologia Anthropologica" have been taken, have now been accepted for custody by the British Museum (Bloomsbury).

THE PLANT ALKALOIDS

The Plant Alkaloids
By Dr. Thomas Anderson Henry. Third edition. Pp viii + 689. (London: J. and A. Churchill, Ltd., 1939.) 42*s*.

IN spite of the fact that modern fashions in chemical research have inclined towards the hormones and vitamins, much work has been accomplished during the past twenty years in the field of the plant alkaloids. This fact is reflected in the third edition of Henry's "Plant Alkaloids", which to all intents and purposes is a completely new book. It bears little relationship to the second edition published in 1924, although the arrangement of the material on the basis of a chemical classification according to the nuclear structure has been retained. Slight deviations from this plan occur where important biological relationships would be obscured by a slavish adherence to such a plan. On the other hand, the reader is warned against placing too much reliance on such relationships in considering possible structures of new alkaloids with the reminder that sparteine, long known as the characteristic alkaloid of broom tops (Leguminosæ), has also been found to occur in *Anabasis aphylla* (Cheniopodiaceæ) and as an associate of chelidonine in the greater celandine (Papaveraceæ).

The fascinating problem of the biogenesis of alkaloids is illustrated by reference to many of the experiments conducted by chemists under so-called physiological conditions—at temperatures about 25° C., in presence of feeble acidity and using materials known to occur or to be capable of formation in the plant. Those of Robinson involving the conversion of lysine and arginine into hygrine, and of Schopf and others on the synthesis of tropinone, pelletierine and lobelanine are typical examples. Such work necessarily follows progress in the correct diagnosis of molecular structure.

Special reference should be made to the section on the alkaloids of cinchona. Numerous and complicated as they are, the efforts at chemical diagnosis have been successful and in many cases confirmed by synthesis. The complex problems of stereochemistry have been solved and it is natural that the literature covering this field is very voluminous. Dr. Henry, himself an outstanding figure in this work, has managed to condense the matter available into digestible proportions. There is no better summary of the cinchona alkaloids than that found within the pages of this volume.

Probably no other department of chemical endeavour has given rise to so much controversy as the structure of certain of the alkaloids. Mention of morphine, strychnine and berberine emphasizes this point. The author has given a critical account of all the important work on alkaloidal structures and has managed to escape being didactic, whilst giving reasoned assistance in the formation of opinion as to the merits and demerits of opposing contentions. In this respect the book should receive a welcome from all concerned, from the research worker to the honours student.

The pharmacology of the alkaloids has been adequately reviewed, much of the exact work being of recent date. This section has been read critically by Dr. White and will be useful alike to the chemist and the pharmacologist. The importance of such work reaches beyond the confines of the 'pure' pharmacologist on account of the comparatively modern endeavours to relate pharmacological action with chemical and physical properties and thus with molecular structure; that is, chemotherapy in its widest sense not limited by the hampering definition of being concerned only with those products which attack an invading organism. Dr. Henry has directed attention to this aspect of the problem by reference to the work on esterified amino-alcohols as cocaine substitutes in local anæsthesia and to the modified cinchona alkaloids. Such work attracts both the pharmacologist and the chemist, and hence it is a great convenience and help to have chemical and pharmacological summaries and references treated in a single book.

Even a work of this size is inadequate to deal with all facts of alkaloidal work, and some selection was imperative. In this connexion Dr. Henry has rightly chosen to deal very briefly with the methods of extraction from the plants and has been content to refer to the more important papers concerned with the chemical and biological determination in plants and plant extracts. Sufficient references are included to help those interested in this aspect of the subject.

The value of such a work as this depends largely upon the bibliography: this is remarkably complete and includes references published little previous to the date of issue. Numerous tests for the presence or absence of references were made, but in no case was the book found wanting.

In conclusion, this work forms a perfect reference book in its subject, and even if criticism were possible, to criticize would be an act of sheer ingratitude. The enormous amount of work involved in the collection, correlation and interpretation of the huge mass of material available represents scholarship of a high order.

W. H. LINNELL.

STRUCTURE AND FUNCTION

Life and Living

By Frederic Wood Jones. Pp. x + 268. (London: Kegan Paul and Co., Ltd., 1939.) 10*s*. 6*d*. net.

THOSE who have had the opportunity of admiring Prof. Wood Jones's facility and effectiveness as a lecturer will be grateful to him for the publication in a book of some of his recent public lectures. His style of lecturing is particularly well adapted for reproduction in the form of written essays, and these make exceptionally pleasant reading.

While dealing with a variety of subjects, the lectures concern themselves mainly with problems of medical education, and with biological problems raised by the consideration of the relation between structure and function. Biologists who have devised theories to explain the structural organization of living creatures have usually appreciated the difficulty of linking structure and function in a common theory of causation. These contrasting aspects of biological study have in the past, indeed, led to an artificial separation of the two scientific disciplines anatomy and physiology, and this again has inevitably encouraged a somewhat dualistic conception of living organisms. Prof. Wood Jones is intent upon the destruction of such an illusion, and would re-orientate the teaching of anatomy so as to stress the fact that structure is only the ultimate expression of function.

Prof. Wood Jones's own views are frankly Lamarckian. For him the precision and consistency with which structures, developed in embryonic life, are adapted for their ultimate function are not intelligible unless the inheritance of acquired characteristics is postulated. Yet even he finds remarkable instances of a disharmony between structure and function. The formation of a median vagina in marsupials, according to his interpretation, was a last-minute effort on the part of Nature to avert a catastrophe which was nearly brought about in metatherian evolution by the fact that the initial vaginal canals were too small to allow parturition to occur. He conceives, also, that by some sort of morphological accident the vertebrate eye during early phylogenetic development became caught up with the infolding medullary tube and inadvertently buried. By good fortune, however, it managed to "struggle" towards the surface again, but only at the expense of becoming inverted, and therefore less perfect as a piece of apparatus than it might have been.

Such instances are here quoted to illustrate the fertility of the author's mind, a fertility which expresses itself in many original ideas and novel interpretations. We cannot but feel that all biologists and many other scientific workers will derive very considerable pleasure and intellectual exercise from reading these lectures.

SCIENCE AND PRACTICE OF FODDER CONSERVATION

The Science and Practice of Conservation Grass and Forage Crops. By Dr. S. J. Watson. In 2 vols. Vol. 1. Pp. xi + 415. Vol. 2. Pp. vii + 417–820. (London: *Fertiliser and Feeding Stuffs Journal*, 1939.) 2 vols., 30*s*.

FARM animals are wintered on fodder and root crops, supplemented by concentrates, that is, grain, milling offals, oil-seed residues, etc.; the fodder, roots, and frequently the grain also are home grown. The preservation of the fodder crops, for use in the winter, presents more difficulties than that of the other home-grown foods, and the quality of the product is very variable, depending on the kind of crop, its stage of maturity when cut, etc. The quality of the product is important, because it governs the amount and kind of concentrates that have to be purchased.

Two recent developments, the improvements in the technique of making silage, and the application of artificial drying to grass and other fodder crops, have aroused much interest among farmers and research workers in fodder conservation, since they have resulted in widening the range of crops for preservation, and also in making it possible to preserve them at a younger stage; these developments have brought within reach of the farmer fodders of higher nutritive value, and with a greater proportion of proteins.

On the Continent of Europe, the new and improved methods of making silage have resulted in the preservation, for use in winter, of large areas of clover, or of grass and clover mixtures, while in Great Britain interest has been aroused in the conservation of young pasture grass by artificial drying, and by ensiling. Young grass contains up to 20 per cent, or more, of crude protein in the dry matter, and its conservation would dispense with the need for purchasing most of the concentrated foods now fed to cattle, sheep and horses.

It can be readily understood how important this possibility is in a country like Great Britain, which is so suited by climatic and other conditions for producing grass Even in the United States, where there are such ample supplies of grain and of some oil-seed residues, much interest is shown in the possibility of reducing the requirements of concentrates by improvements in the quality of fodders.

Dr. S. J. Watson, in "The Science and Practice of Conservation", has brought together, from all parts of the world, the results of research and practical experience in fodder conservation, and the two volumes present an excellent account of the state of knowledge on all aspects of the subject. The first volume deals with the various processes of conservation, natural drying, artificial drying, and ensilage; separate chapters are devoted to the losses of nutrients in each of these processes. The author directs attention to the heavy rate of losses in haymaking, pointing out that the losses are really heavier than are commonly supposed because of the failure to realize that the actual loss of feeding value exceeds that of the dry matter, since the material lost is the most digestible part.

Silage-making occupies a large share of the volume. Before discussing the old and the new methods, the author deals fully with the principles underlying the making of silage. Although the crops for ensiling and the climatic conditions vary from one country to another, the fundamental requirements of successful silage-making are the same, and this volume gives the research worker the type of information that will help him to solve the problems involved in directing the chemical and biological changes in the material in the desired direction.

The second volume deals with the nutritive values of the various conservation products, and contains accounts of the numerous feeding trials reported in the literature. One chapter is devoted to the effects of conservation products on dairy produce, a subject of great importance in peace time in those countries exporting cheese and butter. The last chapter is devoted to the place of conservation in agricultural practice at home and abroad, and deals also with its effect in cheapening the costs of foods for human consumption, and in improving their quality with regard to the health of the nation.

Dr. Watson, by reason of the large amount of research that he has carried out on this subject at Jealotts' Hill, and of his contacts with the practical aspects of the problems, is well qualified to undertake the writing of such a work. Both volumes are of great value to all those interested in fodder conservation, and can be particularly recommended to those engaged in research investigations touching any aspects of this subject.

E. J. ROBERTS.

THE BRITISH EMPIRE CANCER CAMPAIGN

BY DR. E. BOYLAND,
THE ROYAL CANCER HOSPITAL, LONDON

THE publication of the sixteenth annual report of the British Empire Cancer Campaign was very little delayed by the outbreak of hostilities, and the report has appeared in its usual form and is actually larger than it has ever been before. During the War as much cancer research as possible will continue, so long as the scientific workers concerned are not all required for emergency work. There is no doubt that the greatest progress in cancer research has been made in Great Britain and in the United States. Government support and large endowments in the United States are likely to increase American cancer research in the future, and it is to be hoped that the British effort will not fall off.

Among the clinical accounts in this report is a description by Mr. J. P. Lockhart-Mummery and Dr. C. E. Dukes of the familial adenomatosis of the colon and rectum and its relationship to cancer. Adenomatosis is an inherited disease, which is not generally manifested until childhood or puberty. The malignant disease which frequently develops from this adenomatosis occurs at a relatively early age and often has multiple foci of carcinoma. The adenomatosis appears to be transmitted by both sexes, probably as a Mendelian character.

Much of the clinical work describes the results of radiological treatment. Such material is given in the reports of the Westminster Hospital, St. Bartholomew's Hospital, the Marie Curie Hospital and the Mount Vernon Hospital. One interesting development of research on radiations is the discovery of the rhythmic or periodic variation in their action on colloids. If colloidal solutions of carbon, graphite, quartz, gold or albumin are irradiated with a certain dose of neutrons, X-rays, γ-rays or by ultra-violet light, they are coagulated, but if the dose is increased by a certain amount no coagulation occurs. With increasing amounts of radiation, the effect on coagulation alternately increases to a maximum and then falls to zero. This appears to be a periodic phenomenon analogous to the formation of Liesegang rings, and it would be extremely interesting to know if the same periodic variation occurs in the irradiation of living tissues.

At the recently formed Cancer Research Centre of the University of Oxford, Dr. I. Berenblum, Dr. E. Chain and Dr. N. G. Heatley have investigated the metabolic activities of very small amounts of surviving skin epithelium in a micro-respirometer. This tissue shows aerobic glycolysis and has a respiratory quotient of 0·7, properties which at one time were considered to be peculiar to tumour tissues. In fact, the current report from the Royal Victoria Infirmary, Newcastle-on-Tyne, contains the following rather misleading statement. "There appear at the present time to be two main points in which the metabolism of cancer differs from that of most normal tissues. First the ability of cancer cells to form lactic acid persists even when the tissue is respiring, secondly cancer tissue has a respiratory quotient indicating that the oxidation of carbohydrate is abnormal." Since Warburg discovered that slices of malignant tissues produced lactic acid from glucose in the presence of oxygen, retina, smooth muscle, striped muscle, liver, cartilage, bone marrow, lymph glands, kidney medulla and skin have also been shown to glycolyse aerobically. It is therefore impossible to consider this characteristic to be peculiar to tumours. Neither is the lowered respiratory quotient specifically characteristic of malignant tissues.

It was known that the magnitude of respiration and glycolysis did not vary greatly in tumours of different rates of growth, and now Dr. E. Boyland and Mrs. M. E. Boyland have shown that this holds even with enormous variations in growth-rate and that it is possible to inhibit the growth of sarcomata in mice without significantly reducing the respiration and glycolysis as measured *in vitro*. Thus the largest metabolic processes do not vary with rate of growth; this suggests that some tumours must be extremely inefficient in obtaining energy for growth from carbohydrate.

Experiments on carcinogenesis are described in several of the reports. At St. Bartholomew's Hospital, 1 : 2 : 5 : 6-dibenzanthracene in olive oil was introduced into the stomachs of mice in an attempt to produce cancer of the alimentary tract. No alimentary tumours were produced but 95 per cent of those mice which survived the period of injection died with pulmonary tumours. Only minute amounts of the carcinogenic compound could have reached the lungs, and the experiment indicates that the lungs are very sensitive to the tumour-inducing action of dibenzanthracene and that the tissues of the alimentary canal are very resistant.

Other experiments showing the amounts of carcinogenic agent necessary for tumour production were carried out by Dr. P. M. H. Browning at

Glasgow. In these the injection of 0·0025 gm. of 2(*p*-amino-styryl) 6(*p*-acetylamino benzoylamino) quinoline methoacetate ('Styryl 430') into mice was necessary to produce sarcomata, while even with 0·0005 gm. a small coloured depot may be found more than a year after injection. Many other trypanocidal compounds related to Styryl 430 have been tested, but as yet this is the only known compound of its type with carcinogenic activity.

Mr. J. C. Mottram, at the Mount Vernon Hospital, has used the sensitivity of Infusoria to demonstrate the photo-oxidation of carcinogenic compounds. On the whole, the carcinogenic compounds are easily oxidized in ultra-violet light to water-soluble toxic products, and there is rough but not exact parallelism between this action and carcinogenic power. Similar results were obtained some years ago by Dr. E. Boyland, who examined the effect of photo-oxidation products on the enzyme lactic dehydrogenase. The chemical changes which carcinogens undergo in ultra-violet light in the presence of oxygen are still obscure, but Prof. J. W. Cook and Mr. R. Martin of the Royal Cancer Hospital have isolated the photo-oxide of 9 : 10-dimethyl-1 : 2-benzanthracene. The parent hydrocarbon, 9 : 10-dimethyl-1 : 2-benzanthracene, has very high carcinogenic activity, producing epithelial tumours in mice in thirty-five days; 5 : 9 : 10-trimethyl-1 : 2-benzanthracene, however, is now the most active compound and has given skin tumours in thirty-one days in tests carried out at the Royal Cancer Hospital. Derivatives of 1 : 2-benzanthracene with substituents in the 9 and 10 (meso) positions not only give more stable photo-oxides but also more stable maleic anhydride derivatives; thus Dr. L. D. Parsons and Mr. F. L. Warren find that the α-β-endosuccinate of 9 : 10-dimethyl-1 : 2-benzanthracene is very stable and is not carcinogenic, while the corresponding derivative of methylcholanthrene dissociates and is actively carcinogenic. These results indicate that the action of these water-soluble carcinogenic compounds is due to their ability to dissociate and liberate the parent hydrocarbon after injection rather than to the action of the water-soluble compound *per se.* These water-soluble carcinogenic compounds cause lysis of red blood cells *in vitro*, but this action is also shown by similar derivatives of some compounds which have no carcinogenic action.

Dr. P. A. Gorer at the Lister Institute has investigated immunity within pure lines of inbred mice. While it is relatively easy to produce immunity to a tumour in mixed stock animals it is extremely difficult to demonstrate immunity within a pure line. With two types of leukæmia which have been maintained in the pure lines in which they arose, it has not been possible to produce immunity within the homologous pure strain. The response of grafted embryonic tissue is similar to that of neoplastic tissues and different from that of placental tissue, which will not grow even in mice of the homologous pure line; but in general the defence reactions to implanted tissue are governed by genetically determined antigenic differences between the implanted tissue and the host. Experiments on resistance to the Jensen rat sarcoma carried out at the Middlesex Hospital by Prof. S. Russ and Dr. G. M. Scott have shown that the immunity induced by treatment of tumour-bearing rats with X-rays is inherited by the offspring. This appears to be an example of inheritance of an induced or acquired character.

By far the largest individual account in this year's report is that from Dr. P. Stocks, of the General Register Office, Somerset House, on the distribution of cancer of various organs in England and Wales. This account, which is the third and concluding instalment, deals with the cancer mortality of the female population and is more of the nature of a scientific paper than an interim report of work in progress. The standardized mortality ratios for separate towns and counties have now been computed and the results are given in a series of tables and maps. As would be expected from analogous investigations, the mortality from cancer of all sites varies much less than the mortality due to cancer of particular sites. Thus the cancer mortality of part of Wales (Anglesey, Carnarvon, Denbigh, Flint and Merioneth) and of Lincolnshire is higher than that of the rest of the country; but the excess mortality is only of the order of 15 per cent. The high cancer mortality of North Wales is entirely accounted for by an excess of stomach cancer, affecting both sexes. Dr. Stocks suggests that this excess, which is about one and a half times the expected mortality, is due to dietary factors. It is hinted that the bulk of the North Wales population does not consume sufficient vegetables and fruit, and uses the frying-pan too frequently. If this mortality from gastric cancer could be reduced, people escaping might contract cancer at some other site, which might be more amenable to treatment, and some of them would probably avoid cancer altogether.

In the results are several examples of low mortality from cancer of one particular site being compensated for by excessive incidence at some other site. Thus there is a high incidence of uterine cancer in the north-east of England, and in this area cancer of the breast is correspondingly low. Analogous differences are found in the social classes. The incidence of cancer of the uterus in married women decreases steadily with rise in social class, while cancer of the breast is more frequent in the upper classes. This may be connected with birth-rate, as fertility varies inversely with income. Also it is known that countries with high birth-rates tend to have higher relative proportions of uterine and lower proportions of breast cancer; cancer of the mouth, pharynx, œsophagus, skin and vagina, like uterine cancer, are more common in the lower classes, while cancer of the ovary and thyroid, like breast cancer, are more common in the upper classes.

For almost all sites of cancer that are examined (except cancer of the ovaries) the urban incidence is higher than that in rural districts. The figures for cancer of the lung in different districts are difficult to explain; the incidence being very high in Manchester, Leeds, Sheffield and Birmingham, but low in other towns in Lancashire, Durham and Stoke-on-Trent.

The results of Dr. Stocks's investigations have been dealt with at some length partly because it is conceivable that men of science who are not specially working at the cancer problem might see some explanation of the regional distribution of cancer mortality. Such explanations might give rise to fruitful research on the cause of the disease at a particular site.

Until the outbreak of war, British cancer research had been increasing in its extent and effectiveness, as is clearly shown by the annual reports of the British Empire Cancer Campaign. Let us hope that the work will continue and that the present position will be consolidated and extended in the immediate future.

MACROMOLECULES

SOME developments in the chemistry and physics of macromolecules were discussed at a recent meeting of the Plastics Group of the Society of Chemical Industry and the Faraday Society. Many fundamental problems were raised in the papers contributed by Dr. R. Bhattacharya, E. G. Couzens and H. W. Melville, and in the subsequent discussion; only a few can be referred to in the present article.

In the synthesis of macromolecules from vinyl derivatives of the general type $CH_2 = CXY$, much controversy has arisen about the nature of the active polymer molecules which react with the monomer. Two extreme types may be recognized. The monomer may be converted by absorption of energy to a diradical. To each end of this molecule monomeric molecules may add on, giving rise to a bigger diradical. This may be called the free radical mechanism. On the other hand, the monomer may merely be excited to an extent such that the addition of monomer is facilitated. In this mechanism there is always a terminal double bond in the macromolecule which is the centre of reactivity. It would now appear that it is possible to polymerize one and the same molecule by either mechanism, depending on conditions.

The difficulty really arises in discovering in any one instance which particular mechanism comes into operation. In gas phase polymerization it is often possible to settle the matter in the following way. Hydrogen atoms or methyl radicals add on readily to vinyl derivatives, such as vinyl acetate, producing a single free radical with which monomer easily reacts to form a linear polymer until two such radicals combine. By altering various parameters, it is then easy to characterize this free radical growth and compare it with the polymerization under observation. If the kinetics are identical, it must be supposed that the latter reaction is of the free radical type. In the photo-polymerization of gaseous vinyl acetate, the kinetics are so different from those of the free radical reaction that it would seem the ordinary polymerization occurs by some double-bond mechanism. The difficulty yet to be solved is how the terminal double bond of the active molecule retains its activity. It is well known that a large number of these molecules, including vinyl acetate, also polymerize in the liquid phase, but so far no similar attempt has been made to discover by what mechanism the molecules grow, though it is of interest to mention that a free radical polymerization has been induced in styrene by the addition of tetraphenylsuccinodinitrile, which dissociates to free radicals in solution.

From the photochemical point of view, vinyl ketones are of especial interest. Both methyl vinyl ketone ($CH_2 = CH.CO.CH_3$) and methyl isopropenyl ketone ($CH_2 = C(CH_3).CO.CH_3$) polymerize on illumination with light at 3000 A., though the former molecule does so much more readily than the latter. Once more this is in accord with the general observation that α-methyl substituted vinyl derivatives are more difficult to polymerize than the parent molecule. Methyl vinyl ketone exhibits rather peculiar behaviour. Like most gaseous ketones, it is decomposed by light, and therefore in considering the mechanism of polymerization, it is not impossible that, besides the two mechanisms mentioned above, another must be taken into account. The primary products of decomposition may well be free radicals, in which circumstance they may start off a free radical polymerization. Here a comparison of the kinetics of the methyl radical sensitized reaction with the direct reaction shows that the latter reaction does in fact take place by the free radical mechanism, initially started by the photo-decomposition of the methyl vinyl ketone molecule. The product of the reaction is, however, insoluble in all solvents, which points to the fact that the molecule is extensively cross-linked. This is reflected too in the abnormal kinetics of the reaction, in that at high enough pressures the order may be as much as five and the negative energy of activation is a function of temperature, whereas in any ordinary photo-reaction the order is rarely greater than two and the rate may only vary exponentially with temperature. Such kinetics can only be explained by postulating branching of the growing molecules—by what precise mechanism is not known. This is the first simple molecule to be studied in which so-called kinetic as well as structural branching have been observed simultaneously.

This introduces the problem of correlating the properties of macromolecular substances with their structure and mode of synthesis. Even correlation of structure and properties is difficult with natural and synthetic polymers. Probably the two most important groups of molecules to be considered in this respect are (*a*) cellulose and its derivatives, and (*b*) vinyl polymers. In neither case is it possible to account quantitatively for the relatively poor mechanical properties, such as tensile strength and modulus of elasticity, as compared with the values calculated theoretically on the assumption that these properties are wholly dependent on the nature of the primary valencies existing in those macromolecules. This is to be expected to some extent, because in any test it is impossible to determine the properties of an adlineated bundle of molecules in view of the small size of even the largest of such linear molecules. The forces which determine these physical properties must therefore consist largely of an intermolecular variety the magnitude of which is exceedingly difficult to compute.

Matters are much more complicated when an attempt is made to define accurately terms such as toughness, and to correlate this with molecular architecture. Practical experience soon singles out those polymers which are generally recognized as tough, with the result that the consensus of opinion appears to be that toughness is a complicated function of impact resistance, tensile strength, extensibility, Young's modulus and bending strength. Some of these properties are in themselves difficult to determine by unequivocal methods. None the less, it is practicable to gain a qualitative idea of the type of molecule most suitable for any given purpose. Such studies will no doubt eventually provide the material for putting the subject on a more scientific basis. But a useful working criterion appears to be given by the total area under the so-called Schopper curve. This is a curve obtained by plotting the load on a material as a function of the percentage elongation. With those plastics normally regarded as tough, for example, cellulose nitrate and acetate, ethyl cellulose suitably plasticized, the curve rises rapidly and then flattens out over a considerable elongation. The triacetate and nitrocellulose are particularly good in this respect. For the exhibition of high extensibility, however, all these molecules must be plasticized, but experiments with other cellulose have shown that a plasticizer is not really necessary if, say, ethyl groups replace the hydrogen atoms of the hydroxyl groups. Unfortunately, the tensile strength of ethyl cellulose is inferior to that of nitrocellulose. Vinyl compounds, on the other hand, do not show this high extensibility, although vinyl chloride is regarded as being very tough. The great extensibility of the cellulose derivatives can be simulated if appropriate side chains are added to the molecule as in polyvinyl butal, but at the expense of a decrease in tensile strength. The addition of plasticizers does not improve matters, as with cellulose, for then the material loses its resistance to deformation and becomes rubber-like in character.

Progress in this field is greatly hampered by the fact that the molecular weights and molecular size distribution are not known for the majority of these polymers. The viscosity method of Staudinger is the only one which is used extensively for large linear molecules, but the discrepancies brought to light when the results obtained with this method are compared with those from end-group determination and by osmotic methods show that all is not well. In view of these difficulties, attempts have been made to modify the simple Staudinger relationship that the specific viscosity of the solution is proportional to the molecular weight of the dispersed phase, but with only limited success. A striking example of the enormous influence of the solvent is shown by the fact that a twenty per cent solution of cellulose in acetone is easily pourable, whereas a similar solution in dimethyl phthalate forms a stiff gel. Part of the trouble would seem to lie in the sensitiveness of specific viscosity to the distribution of molecular sizes in the polymer. Moreover, it is just this factor which is so important in influencing the physical properties mentioned above. It seems to be a general rule, however, that properties such as tensile strength and Young's modulus increase to a rough maximum with increase in molecular weight. The absolute value of these quantities depends on the nature of the side groups. Those groups exhibiting relatively small interactions, such as phenyl, lead to weakness, while hydroxyl, formal, acetal groups and chlorine atoms yield stronger polymers even although the length of the carbon chain is identical in both cases.

All this work has had its effect on improving natural resins by systematic methods. Shellac may be cited as a typical example. It consists of a saturated pentahydroxy monobasic acid of partially known constitution and molecular weight of about 1,000. As such the substance is of no use as a plastic, but it may be modified to give a great variety of useful products. On heating, it may be polymerized to linear molecules of much higher molecular weight. That this is due to interaction between hydroxyl groups and carboxyl groups of different molecules is shown by the fact that, if either of these groups is chemically bound to other small molecules, such as by the formation of ethers or esters, this polymerization will not take place. By further heat treatment the shellac may be made insoluble, owing presumably to the cross linking which can occur by means of the multiplicity of hydroxyl groups in the 'monomer'. If, however, these hydroxyl groups are modified by reaction with ethylene glycol, this reactivity is cut down to such a point that cross linking is impeded. The result is that much longer linear molecules may be formed with molecular weights up to 25,000. The polymerized lac is then a tough flexible rubber-like substance. Interpolymerization of shellac with naturally occurring unsaturated resins gives rise to a product similar to drying oils used in paints. Further, such composite molecules may be induced to react with formaldehyde to give complex cross-linked molecules of desirable film-forming properties.

CARBON DIOXIDE IN ARCTIC AND ANTARCTIC SEAS

By Dr. G. E. R. Deacon,
"Discovery" Investigations

FOR many years past, Prof. K. Buch of the Åbo Akademi, Finland, has been leading the research on the distribution of carbon dioxide in the sea and its interchange between sea and atmosphere, and lately by a survey of the surface waters of the North Atlantic Ocean[1] he gives a very clear demonstration of the value of his methods.

Less than one per cent of the carbon dioxide in the sea is in ordinary physical solution, the greater part being there as carbonate and bicarbonate ions. First there is an equilibrium between dissolved gas and $H^{\cdot}$ and HCO_3' ions, and then between HCO_3', $H^{\cdot}$ and CO_3'' ions, both reactions being influenced by temperature and pressure, and by the concentration of the other ions present, particularly $Ca^{\cdot\cdot}$, $Na^{\cdot}$, $Mg^{\cdot\cdot}$ and SO_4''. The behaviour of sea water towards carbon dioxide is therefore very different from that of fresh water: it acts as a buffer solution, and a comparatively large volume of carbon dioxide can be absorbed or given up at the surface without much change in the concentration or partial pressure of the part of the gas that is in physical solution.

Buch and his collaborators had already reached the important conclusion that the equilibrium between dissolved and combined carbon dioxide is fully determined by hydrogen ion concentration, temperature, pressure and alkalinity (as measured by titration)[2]: if these are known, the partial pressure of dissolved carbon dioxide and the concentrations of HCO_3' and CO_3'' ions can be calculated; and since Wattenberg has shown that alkalinity is in general proportional to chlorine content[3], it is sufficient to know temperature, pressure, hydrogen ion concentration and chlorine content.

Buch's recent observations cover practically the whole of the North Atlantic, from Denmark and New York as far as the Arctic pack-ice; but they were all made during the summer months. His calculations based on *p*H measurements, amply confirmed by direct analyses, revealed the remarkable fact that the carbon dioxide content of the surface water (free plus combined carbon dioxide), in any part of the extensive region examined, bore a constant relation to alkalinity, and therefore to chlorine content and salinity: expressing the total carbon dioxide of any sample in millimols per litre, he found the expression $\Sigma CO_2 = 0{\cdot}108\ Cl^{0}/_{00} \pm 1{\cdot}5^{0}/_{0}$.

This means that the total concentration of carbon dioxide in the surface water was controlled within very narrow limits until it had a certain relation to the power of the water for combining chemically with carbon dioxide.

Biological activity and vertical mixing with the deeper water will have an effect on this relation;

a diatom outburst will lower the carbon dioxide content, while the upwelling of deeper water or a rich zooplankton will cause an increase. The fact that Prof. Buch's observations were all made during the summer months must therefore be emphasized; and attention given to his reasoning that in winter, when the phytoplankton activity is very small and vertical mixing greatly increased, the carbon dioxide may bear a higher ratio to chlorine.

Type of Surface Water	SUMMER Nov. 23–March 18, 1938–39					WINTER July 2–Sept. 26, 1938				
	Number of observations	ΣCO_2 m.mol/l.	ΣCO_2 Cl‰	pCO_2 10^{-4}atm.	O_2 % sat'tn.	Number of observations	ΣCO_2 m.mol/l.	ΣCO_2 Cl‰	pCO_2 10^{-4}atm.	O_2 % sat'tn
Subtropical (south of 35° S.)	13 11·8° C. to 21·5° C.	2·04 1·99–2·09	0·104 ±3%	2·8 2·4–3·8	96 93–100	11 11·4° C. to 18·6° C.	2·08 2·05–2·11	0·107 ±2%	3·2 3·1–3·5	92 89–95
Sub-Antarctic	22 3·7° C. to 17·6° C.	2·06 2·02–2·09	0·108 ±3%	3·0 2·6–3·5	98 94–99	17 3·9° C. to 12·4° C.	2·09 2·07–2·12	0·110 ±2%	3·3 2·9–3·5	94 92–95
Antarctic (north of 57° S.)	17 −1·8° C. to 2·9° C.	2·10 2·08–2·13	0·112 ±1%	2·9 2·3–3·6	95 90–99	18 −1·8° C. to 2·0° C.	2·14 2·11–2·17	0·114 ±1%	3·3 3·1–3·6	91 85–94
Antarctic (south of 57° S.)	23 −1·4° C. to 1·3° C.	2·10 2·06–2·13	0·112 ±1%	2·6 2·3–3·6	95 90–102					

This is proved in the Southern Ocean by repeated observations made by the R.R.S. *Discovery II*[4] in the sector between 0° and 20° E., summarized in the accompanying table. In some contrast to the conditions in the North Atlantic, it was found that the $\Sigma CO_2/Cl$ ratio increased from low to high latitudes, and subtropical, sub-antarctic and antarctic waters were found to have their own typical ratios. Extreme values in each zone were found to overlap with those of the next; but there was sufficient grouping about the mean values to give them significance, and the existence of such typical values for each zone is not unlikely because biological activity and vertical mixing depend on sunshine, concentration of nutrient salts, stability of the upper part of the water column, and strength and variability of wind, all of which are to some extent determined by latitude and by the hydrographical conditions typical of the zones. In the part of the subtropical zone that was examined, and in the sub-antarctic zone, the variations of the extreme values about the means were greater than Buch's figure of 1·5 per cent for the North Atlantic, but the upper part of the water column is less stable.

Prof. Buch's papers contain much more information. Although the salinity of the water in a particular region will fix the total carbon dioxide content, the proportion of dissolved to total carbon dioxide will vary with temperature, and the partial pressure of the dissolved gas (the pressure of carbon dioxide in an atmosphere in equilibrium with the water) must show a still greater variation because it depends on the solvent power of the water, which is greater at low temperatures.

Near the Arctic pack-ice Buch found (as the ratio $\Sigma CO_2 = 0{\cdot}108 Cl°/_{00}$ demands) partial pressures of carbon dioxide in the surface water as low as $1{\cdot}6 \times 10^{-4}$ atmosphere—about half the pressure which is needed to satisfy the same relation for total carbon dioxide in the warmer and more saline waters of the temperate region. The partial pressure of carbon dioxide in the air above the ice-edge was 3×10^{-4} atmosphere; but the wind was blowing southwards off the ice and had not reached an equilibrium with the water; by the time it had passed over some 100–200 miles of the open sea, its partial pressure of carbon dioxide was reduced to $1{\cdot}6 \times 10^{-4}$ atm.—as low as that of the water. The air in the polar region—derived from upper-air currents which have their origin in temperate regions—has apparently a normal carbon dioxide content, but in summer at least it is greatly modified during its passage across the fertile Arctic fringe, and even as far south as Iceland and Petsamo, 'Arctic air' can be distinguished from winds of temperate and continental origin by its low carbon dioxide content.

In the Antarctic sector between 0° and 20° E. the partial pressure of carbon dioxide was not found to fall as low as Buch's Arctic values; but although the figures in the accompanying table appear to be typical of the greater part of the Antarctic Ocean, the conditions in the more sheltered localities are very like those of the Arctic. In such places the $\Sigma CO_2/Cl$ ratio becomes reduced below any value shown in the table, and, for example, in the Bay of Whales in the Ross Barrier, off the west coast of Graham Land, at the edge of the pack-ice after exceptionally long spells of fine weather, and near South Georgia at a time of exceptional phytoplankton activity, the partial pressure of carbon dioxide in the surface water has been found to be as low as $1{\cdot}6 \times 10^{-4}$ atm.—the same as at the Arctic pack-ice.

The only determinations of atmospheric carbon dioxide in the Antarctic appear to be those quoted by Buch[5], from the results of one of Charcot's expeditions to the west coast of Graham Land: ten samples ranged from $1{\cdot}45 \times 10^{-4}$ atm. to $2{\cdot}55 \times 10^{-4}$ atm., with an average of $2{\cdot}26 \times 10^{-4}$ atm.

The *Discovery II* observations show that the low carbon dioxide pressures are likely to be found only in the summer months: in winter the $\Sigma CO_2/Cl$ ratios were so high that even the freezing water had carbon dioxide partial pressures of at least $3{\cdot}1 \times 10^{-4}$ atm.

It has not been possible in this short article to do justice to the earlier workers on the carbon dioxide problem, notably Prof. A. Krogh and J. F. McClendon, or to describe recent work in the Barents Sea and the Baltic, and more particularly Prof. Wattenberg's treatment of the *Meteor* observations, but enough has been said to show what great opportunities the accurate measurement of hydrogen ion concentration in the sea offers.

It may, for example, be worth while to review what has been done on the relations between animal behaviour and alkalinity in the sea, because carbon dioxide concentration may be as effective in governing shoaling and distribution as hydrogen ion concentration; there are also many outstanding problems relating to the decomposition of plankton that can be re-examined by calculating carbon dioxide concentration from hydrogen ion concentration measurements; the Discovery Committee's data will help to solve some of them.

Carbon dioxide determinations have also geophysical and climatological interest. Since the ocean has such a tremendous capacity for carbon dioxide, it must, practically speaking, control the carbon dioxide content of the atmosphere, and where equilibrium with the surface water is established the atmospheric carbon dioxide pressure will depend to some extent on biological activity and distribution of nutrient salts; the low carbon dioxide pressures around the polar fringes in summer give these regions an added attraction. Continental air has generally a high carbon dioxide content; but Prof. Buch shows that modern development can have very little influence on the total carbon dioxide content of the atmosphere, and his figures are refreshing, as his papers are.

OBITUARIES

Sir Gilbert T. Morgan, O.B.E., F.R.S.

SIR GILBERT MORGAN died after a very short illness on February 2 in his seventieth year. For fifty years he had been engaged in chemical research and probably no other chemist had such wide knowledge of scientific and applied chemistry. A fitting mark of the Jubilee was the presentation to him in July last of the medal of the Society of Chemical Industry, its highest honour; on this occasion he gave an account of his career and an outline of his researches.

A professor to-day has the advantages of laboratories and equipment such as were never dreamed of by his forebears; he is more dependent than they were on his research students and collaborators. Morgan was happy in this respect; he gave full credit, developed the personal side and received the most loyal support. This in part accounts for the great volume of work accomplished.

Handsome, with alert and friendly eye, yet quiet in manner, Morgan had an amiable personality. He was wedded to chemistry, and when not at the laboratory bench or directing research he was to be found working for one or other of the chemical societies. In their more sociable gatherings he had the gracious assistance of Lady Morgan, *née* Kathleen Desborough.

Morgan was a student of Meldola at Finsbury and came under the practical teaching of Streatfield, who has influenced so many chemists. Meldola was then working on dye stuffs and consulting for Read Holliday at Huddersfield, who found a post for Morgan at the end of his college career.

Here a wide field was open for research, and among other tasks, Morgan prepared the ten dihydroxynaphthalenes, which took him four years. He relates that he condensed formaldehyde with phenol to a product which solidified to a clear amber resin. As the material had no value for making colours it was set aside. This was in 1893, and it was not until 1906 that Bakeland patented the process as a synthetic resin and made a large fortune out of it.

In 1894 Morgan became restless in industry and went back to college, graduating at the Royal College of Science under Sir William Tilden and being appointed to the staff there. In 1904 he began the fruitful co-operation with Miss Micklethwait leading to work on organic derivatives of phosphorus, arsenic and antimony.

Morgan passed on to the Royal College of Science, Dublin, where he was at the outbreak of the War of 1914–18. In 1915 he went back to his old firm, now British Dyes, for a short period to help reconstruct the industry. But in 1916 he returned to academic life and to Finsbury to succeed Meldola, transferring to Birmingham as Mason professor in 1919. In 1925 came what he described as "a State experiment in Chemical Research", namely the decision to form a Government Research Laboratory at Teddington under the Department of Scientific and Industrial Research, with Morgan as its first director.

It was generally felt that no one was better fitted for the task, but opinions were sharply divided as to the nature of the work which could best be carried out there. It is widely accepted now that Morgan made a success of the task, and that when he retired after thirteen years he left the Chemical Research Laboratory as an asset of real value to the nation. The work done by the Laboratory during the first few months of the War has fully justified all the hopes which Morgan had for its future, and it was a keen pleasure to him to hand over the directorship to one of his students, Dr. G. S. Whitby.

Morgan organized a variety of work at Teddington, including an installation for high-pressure reactions, a branch of chemistry then in its infancy. His interest in chemical engineering had always been strong, and he did much to develop the autoclave.

Morgan's scientific researches cover so wide a field that any reference to them in detail here is impossible for lack of space. Their very diversity prevented perhaps the highest achievement in any one field, though all were fruitful to a greater or less extent. Morgan's claim to fame rests on broader foundations. He did as much as anyone to place the science of chemistry on a sure basis in Britain. By teaching and research, by co-operation with industry, he inspired men to succeed in solving chemical problems and advanced the national status and prestige in chemistry, pure and applied.

At a moment when most men would have sought ease, he was ready to start again in a new branch of his subject as chairman of the Research Fund Committee, Institute of Brewing. He received numerous honours, a knighthood in 1936, honorary degrees at Dublin, Birmingham, St. Andrews, the fellowship of the City and Guilds Institute, to mention only a few. He was formerly president of the Chemical Society and of the Society of Chemical Industry, and an indefatigable worker on committees.

We have lost his kindly presence and the help of his clear incisive mind all too soon. A life crowded with change and incident may have caused him to live faster than some of us; we could have wished for his ripe counsel in old age.

E. F. Armstrong.

Mr. E. S. Harkness

Mr. Edward Stephen Harkness, the American philanthropist, who died on January 30 just a week after his sixty-sixth birthday, devoted his last score of years to administering and sustaining the benefactions instituted by his mother, who founded the Commonwealth Fund in America in 1918. The Harkness fortune was made in Standard oil. It dates from about seventy years ago, at which time Stephen V. Harkness, the father, who was in a small way of business in Cleveland, Ohio, is said to have lent the daring young Rockefeller £1,200. In the present century the example set by Rockefeller in efficient philanthropy inspired the Harkness family. After the death of the father, mother and son made philanthropy their first interest. The elder Mrs. Harkness died in 1926, leaving for the Fund an endowment of about £7,500,000, which sum Edward Harkness later increased to more than £10,000,000. But he also bestowed large personal gifts.

Efforts of the Commonwealth Fund have taken chiefly the lines of education and of public health. In England the first major gift was the fellowships for post-graduate Britons in American universities, the counterpart to the Rhodes scholarships, except that Commonwealth fellows may proceed to any of about twelve universities in America, either between the Atlantic coast and the Mississippi, or on the Pacific coast. The stipend is £600 a year for two or three years; to date appropriations for these fellowships have reached a total of £650,000. Most of the holders have studied science in America—physics, chemistry, biology, engineering. In 1930 Harkness gave to England the Pilgrim Trust, £2,000,000, the first grant from which was given to the building fund of the Royal Institution. The five original trustees of the Pilgrim Trust still serve. A third Harkness philanthropy in Great Britain was the Child Guidance Council, a centre of information upon 'mental health' for children. Recently in Woburn House, the Council is now evacuated to Bath, and is itself at present engaged in an inquiry into "emotional and behaviour problems" of evacuees.

Grants from the Commonwealth Fund in America have taken a general medical turn, following in that subject the pattern of the Rockefeller Foundation, and contributing in the past twenty years about £4,000,000. Part of this sum has subsidized research in trachoma, leukæmia, functions of the kidneys, and bodily resistance to disease. An annual grant has been given to Dr. May Wilson's clinic in New York for rheumatic fever. Large sums have gone on one hand to the advance of medical teaching, and on the other to fellowships for young post-graduates in medicine. Harkness built ten hospitals. In these, mostly in the rural south, as in Virginia and Tennessee, he took a steady personal interest. In one area, Rutherford County, Tennessee, the Fund has for fifteen years served the cause of public health, and has strikingly reduced the death-rate there from typhoid fever, diarrhœa, tuberculosis and puerperal fever together with infant mortality. Only a fortnight before Harkness died he announced the enlargement of two of his hospitals in this region. But apart from this medical philanthropy, Harkness will be chiefly remembered in America for his great gifts to Harvard and Yale Universities—about £6,000,000 altogether—for a scheme under which those unwieldy institutions were enabled to build separate colleges—seven at Harvard and nine at Yale—after the plan of Oxford and Cambridge, and at last give staff and students an opportunity to become individuals.

A reticent and diffident man, Harkness used to say he devoted almost as much time to shunning publicity as to studying philanthropy. A widow survives him, but no children. WILLARD CONNELY.

[It has been announced that Mr. Harkness has left the bulk of his estate, which is believed to exceed 100,000,000 dollars, in trust to his wife. After her death it is to be divided among twelve institutions including: the Commonwealth Fund, the College of Physicians and Surgeons of Columbia University, Harvard University, Yale University, and Atlanta University.]

WE regret to announce the following deaths:

Prof. Alexandre Desgrez, a member of the Section of Free Academicians of the Paris Academy of Sciences, and professor of medical physics in the Faculty of Medicine, University of Paris, on January 20.

Prof. S. J. Hickson, F.R.S., emeritus professor of zoology in the University of Manchester, on February 6, aged eighty years.

Mr. H. I. Smith, formerly chief Dominion archæologist and assistant director of the Canadian National Museum, aged sixty-seven years.

NEWS AND VIEWS

Horace Bénédict de Saussure (1740-1799)

ON February 17 occurs the bicentenary of the birth of the celebrated Swiss naturalist and geologist Horace Bénédict de Saussure. He was born at Conches, near Geneva, in which city he passed most of his life and in which he died on January 22, 1799. As a boy he was a diligent collector of plants and minerals, being stimulated in his studies by his uncle, the naturalist Charles Bonnet (1720–93). At the age of twenty he made his first tour to the glacier of Chamonix, an excursion regarded generally as dangerous. This was the beginning of his many journeys in the Western Alps and his travels in England, Germany, Sicily and Italy. At the age of twenty-two he was given the chair of physics and philosophy at the Academy of Geneva, and this post he held until 1786 when he resigned and was succeeded by his pupil Marc-Auguste Pictet (1752–1825). Among his earliest writings was a volume on electricity published in 1766. Year by year he extended his knowledge of the Alps, and in 1787 on August 2 with Michel Cachet he ascended Mont Blanc. The first Englishman to make the ascent, Mark Beaufoy (1764–1827), reached the summit a week later. In 1788 Saussure spent about a fortnight on Col du Géant and between 1789 and 1792 climbed Monte Rosa, the Breithorn, and other mountains. The upheaval in Switzerland due to the revolutionary movement in France drew him for a time into political life, but in 1794 most of his activities were brought to an end by a stroke of paralysis. From this he never really recovered.

Saussure's great work "Travels in the Alps 1779–1786" was described by von Zittel as a model of clear language, exact observation and cautious reasoning. His "glowing descriptions of the Alpine world removed the prejudice against the 'Montagnes Maudits', and awakened a feeling of enthusiasm for the infinite wonderland of beauty and delight in the higher altitudes of the Alps. Apart from his achievements in science de Saussure may be regarded as the pioneer of a practically new cult in human enjoyment, the love of mountain climbing". As a geologist de Saussure's aim was to observe, and to observe accurately. He examined the mineral composition of the rocks and studied their topographical, meteorological and physical relations on the mountains. He improved the hygrometer and the anemometer and devised a cyanometer and a diaphonometer for comparing the degrees of transparency of the atmosphere at different altitudes. Half a century after de Saussure's stay on the Col du Géant, J. D. Forbes visited the same spot and in 1843 he wrote in his "Travels through the Alps of Savoy" that "No system of connected physical observations at a great height in the atmosphere has ever been undertaken which can compare with that of de Saussure. At any time such self-denial and perseverance would be admirable; but if we look to the small acquaintance which philosophers of sixty years ago had with the dangers of the higher Alps, and the consequently exaggerated colouring which was given to them, it must be pronounced heroic".

A biography of de Saussure was published by Dr. Douglas Freshfield in 1920 and was reviewed by Prof. T. G. Bonney in NATURE of February 10, 1921.

Evacuation and the Schools

LORD DE LA WARR's recent speech as President of the Board of Education in the House of Lords in reply to a motion by the Archbishop of Canterbury has been sent out as an announcement of the Board. It is a timely recognition that educational affairs in Great Britain are not as they should be, and that improvements are needed at once. Granting that the wholesale evacuation of children was a necessary and difficult process, more pains should have been taken to cope with the problems to be faced, one of which, now urgent, is an increase of illness at this time of the year. Every schoolmaster knows the dangers of the Easter term. Things have been done in a hurry and in alarm which should certainly be undone. An important school in a non-danger area was closed until further notice and reopened when better sense prevailed; much of the commandeering or use of school buildings for Government officials or civil defence was unwarranted, and its extent has been reduced.

The President of the Board says nothing of buildings long condemned as unsatisfactory and remaining unrepaired. Children lounging about the streets are a nuisance to themselves and everybody else, and rapidly deteriorate. This misguided leisure is being rectified by the allocating of camps and hiring of extra halls. Authorities have been told that children may be admitted to school before protection is completed. The 400,000 at present "receiving no schooling or care at all" present an urgent problem. In some cases "provision has been made and the children are not attending", and it is stated there are those who "bolster up evacuation by keeping schools closed". The announcement of compulsory school attendance for older children is a step in the right direction. Examinations should go on and full-time schooling be made compulsory as soon as possible. Lord De La Warr realizes that "education is not less important in wartime but more so". At a national conference of secretaries of the National Union of Teachers, a resolution was passed warmly welcoming "the decision of His Majesty's Government to enforce compulsory school attendance in evacuable areas no less than in neutral and reception areas".

Evacuation and Science Work in Schools

THE transference of schools from 'vulnerable' to 'safe' areas in Britain, where they now work in conjunction with other schools of the same type, was a necessary part of the scheme adopted at the outset of the War to minimize loss of life in the event of air attacks upon the civil population. Since last September, normal educational work has therefore not been possible for a very large number of secondary school pupils, and whatever gain there may have been for those from towns coming into closer contact with Nature, it is perhaps offset by reduced teaching and laboratory facilities. Even the better equipped of secondary schools cannot be expected to accommodate double the usual number of science classes, and though in many instances the amount of time devoted to science subjects has not been seriously curtailed, the work is often done in unfavourable circumstances, especially as regards the senior work. It is difficult to accommodate all the senior students in the small advanced laboratories found in most secondary schools even when a system of 'double shifts' is arranged, so that practical work has suffered more than theoretical teaching. The standard of proficiency of pupils who will leave school this year to continue at the universities will be examined with much interest. That the experiment of evacuating schools was a wise one, despite the dislocation involved, there can be no doubt, and the authorities are doubtless watching its consequences so far as secondary and higher education is concerned.

Health of the School Child

SIR ARTHUR MACNALTY's report for 1938 on "The Health of the School Child" has been issued by the Board of Education (H.M. Stationery Office. 1*s*. 3*d*.). The introduction considers the circumstances rendering necessary the evacuation of school children from large urban centres of population and its effect upon the school medical service. During the year the nutrition of 1,674,023 children was assessed at routine medical inspections, and 14·5 per cent were found to be excellent, 74·2 per cent normal, 10·8 per cent subnormal and 0·5 per cent bad. During twenty years, improvement in the nutrition of the school child is striking. Thus in Sheffield, compared with 1920, five-year-old boys average nearly 2 inches taller and 3 lb. heavier, and five-year-old girls 1·4 inches taller and 1 lb. heavier; twelve-year-old boys are more than 2 inches taller and 9¾ lb. heavier, and twelve-year-old girls 3 inches taller and no less than 12·4 lb. heavier. The numbers of children in receipt of free meals or milk continue to increase—from 535,300 in 1936–37 to 687,855 now—and the milk-in-schools scheme is in operation in 87 per cent of public elementary schools. Much information is given respecting medical inspection and treatment, hearing of children, the school dental service, and the care of the young child.

Rhodes-Livingstone Institute, Northern Rhodesia

A BRIEF note on the work of the Rhodes-Livingstone Institute since its inception in 1937 prefaces a contribution on "Anthropology as a Public Service" by Mr. Godfrey Wilson in the current issue of *Africa* (13, 1; January 1940). This Institute, it may be remembered, was founded largely through the efforts and interest of Sir Hubert Young, then governor of Northern Rhodesia, and was the first institute for systematic sociological research to be established in colonial Africa. In the words of the founders, it was intended "as a contribution to the scientific efforts now being made in various quarters to examine the effect upon native African society of the impact of European civilization." In the first instance, funds were asked for three years only, with a view to a special appeal in 1940, a year specially linked with the two men whom the Institute commemorates. It is the centenary year of Livingstone's departure for Africa and the jubilee year of the foundation of the two Rhodesias by Cecil Rhodes.

The Institute is not a Government department but an independent body governed by trustees. Although for the moment the bulk of the income is derived from Northern Rhodesia, contributions are made by all the Governments from Southern Rhodesia to Uganda. Not only has the museum founded in memory of Livingstone in 1934 been incorporated in the Institute, its curator acting as the secretary, but also two research officers have been appointed, of whom Mr. Wilson is one, and the results of their investigations will be published in a series, the *Rhodes-Livingstone Papers*, to which non-members are also invited to contribute.

Pioneers in Amerindian Portraiture

THE February issue of *Man* is a Catlin centenary number, and Mr. L. J. P. Gaskin recalls that on February 1, 1840, George Catlin, artist, traveller and ethnographer, opened his North American Indian Museum and Gallery in the Egyptian Hall, Piccadilly, London (see also NATURE, January 27, p. 158). Catlin was a self-taught artist and ethnographer. By contrast, Paul Kane (1810–71) was an artist by training and profession, and in his home in Toronto he had been familiar with the appearance and dress of Indians of various tribes who visited that seat of government. After travelling in the United States and studying in Europe, he set out on the first of his two expeditions among the Indians in 1845, when he spent five and a half months in recording portraits of "the principal chiefs, and their original costumes to illustrate their manners and customs, and to represent the scenery of an almost unknown country". In 1846 Kane started on his second and more important journey, which occupied two years and six months and extended across the continent to Fort Victoria. He did not keep a journal during his travels, and his book "Wanderings of an Artist among the Indians of North America" (1859) appears to have been written from memory.

Kane's sketches, exhibited on his return, attracted much interest, and a number of pictures were commissioned from him, some by the Government. Some of his pictures are now in the National Gallery, Ottawa, the House of Commons, Ottawa, and the Royal Ontario Museum of Archæology, Toronto. Of his field sketches, some are likewise preserved in Toronto, while a number are in the possession of David I. Bushnell, jun. Reproductions of these have now been published with an account of the artist's life and work by the present owner (*Smithsonian Miscell. Collect.*, **99**, 1; 1940). They show a number of variations, important in an ethnographical sense, from the studio portraits and studies painted later.

Tibetan Ceremonial and the Dalai Lama

SINCE the revelation of the reincarnation of the late Dalai Lama in the body of a small boy and his entry into Lhasa, further observances of the ritual ceremonial have affirmed the youthful succession in his position—in this instance all the more necessary in view of the slight discrepancy between his age and the period of time that has elapsed since the death of his predecessor. Among these is the assumption of the new name or names by which the Dalai Lama will be known officially in future. These are, it is stated (*The Times*, February 9), Jampel Ngawang Lobsang Yishey Tenzing Gyatso, of which the meaning is "Tender Glory, Mighty in Speech, Excellent Intellect, Absolute Wisdom, Holding to the Doctrines, and Ocean-Wide". These names derive from titles of former Dalai Lamas, including the first, which was bestowed by the Mongol prince Yushi Khan.

Large numbers of Buddhist priests and nuns are now present in Lhasa for the installation ceremonies, and have attended the ceremonial performances which have taken place in the courtyard of the Potala, the vast monastic establishment in which the Dalai Lama resides. The important part of the New Year observance, as with many primitive peoples, and also among the more primitive of the European peasantry even to-day, is the ceremonial of driving out all the evil influences of the Old Year. In Tibet this is of especial significance in view of the element of 'devil-worship' which has been introduced into the practices of Tibetan Buddhism, and the ecstatic 'devil-dances' in which its followers indulge more especially in eastern Tibet.

On this occasion, it is reported in a dispatch from Lhasa (*The Times*, February 12), the dancers, wearing masks representing the heads of stags or bulls and grinning skulls with fangs, enacted the reception for the skeleton dance which was performed by four skeleton dancers, with two attendant death's heads, scattering ashes. A magician wearing an apron of bones and a tall black hat topped with a fan-shaped ornament conjured spells from a skull while spinning in a rhythmic dance, which was the preliminary to ceremonies performed over an artificial corpse, which no doubt represented the Old Year, although this is not stated. Fire, as always a purificatory agent, appeared in the ceremonial when pictures of Tibetan devils were burned.

Forgotten Methods of Painting

IN his discourse on "Forgotten Methods of Painting" at the Royal Institution on February 2, Mr. Hesketh Hubbard spoke of the almost forgotten *sfumato* and *botizar* systems of oil painting, and dealt with the method of dusting dry powdered pigment over a sticky mordant which was used by some of the sixteenth and seventeenth century painters for laying certain pigments—a method known as 'strowing'. He outlined the technique of the fourteenth century English painters who worked in water-colour on woven linen; the linen was first saturated with gum-water, and then stretched over coarse woollen and frieze cloths which absorbed most of the colour, leaving the linen transparent after painting. The method of elydoric painting, or painting miniatures in oil whilst the painting ground was submerged in water, and the techniques of encaustic painting were among the topics mentioned.

In his ceaseless search for new pigments, before the chemist rendered him much assistance, the painter had not despised even the food upon his table. The great Paul Sandby himself had converted into pigment burnt crusts and peas that had been cooked to a cinder. Mr. Hubbard said that there is no reason to suppose that the painter has discovered all the manifold uses of his materials; the more media he has at his disposal the less restricted will be the mental outlook of the painter. Every medium of painting shares a frontier with one or more other media. At one point tempera touches fresco; at another it borders on oil painting. Glass painting and enamelling share much in common. It is along these frontiers, in the region of mixed methods, that the painter, in these latter days of painting will, in Mr. Hubbard's opinion, find the most profitable fields for experiment and research. For the same reason, the painter and student might profitably turn their attention, at least in their leisure hours, to some of the forgotten methods of painting.

Lunar Tide in the Atmosphere

THE *Meteorological Magazine* of December 1939 contains a summary by Prof. S. Chapman of his presidential address to the Association for Meteorology at the Washington Assembly of the International Union for Geodesy and Geophysics last September, the subject being the lunar tide in the atmosphere. The author describes the difficulty that was met when the detection of this lunar tide, achieved first by Lefroy in 1842 for St. Helena, was attempted for higher latitudes, which resulted in a succession of failures that was not broken until his own determination in 1918 of the very small Greenwich air tide, from sixty-four years of hourly data. From that year, when the tide was known for three tropical stations and one non-tropical, progress was rapid, and the rate of determination by Prof. Chapman and his assistants was increased threefold in 1930 through a loan of Hollerith machines by the British Tabulating Machine Co. Now the tide has been determined for more than fifty places.

With this number of determinations available for study of the world distribution of phase and amplitude, several interesting peculiarities have come to light; for example, an early maximum is shown at Salt Lake City, San Diego and San Francisco, this being two hours before the upper and lower lunar transits at the last two places, but at the neighbouring high-level stations of Mount Wilson Observatory and Mount Hamilton (Lick) the tide, although similarly small for the latitude, has roughly the normal phase with high tide after the moon's transits, an effect doubtless due to the presence of the great mountain chain of North and South America. Similar effects are, however, not shown by Kodaikanal and Periyakulam, in India, although the heights of those places differ more than do those of the American stations, the differences being as much as 2,249 metres. Equally remarkable is the practically world-wide retardation of the time of high tide in December and January as compared with April or May, in spite of the fact that summer in one hemisphere corresponds with winter in the other. Work has been begun on the determination of the air currents of period equal to half a lunar day that must be associated with the pressure tide; this problem is being attacked with the aid of the long record available at Batavia.

Ultra-Violet and Infra-Red Radiations on the Farm

L. C. PORTER, of the General Electric Company's incandescent lamp department in Cleveland, said, at a meeting of the American Society of Agricultural Engineers held on December 7, that if only electric current becomes cheap enough and suitable equipment is developed, then ultra-violet and infra-red radiations can have many uses on the electrified farm of the future (Science Service, Washington, D.C.). Adaptations of the familiar dull-red glowing electric heaters can readily be made for use in poultry-houses, in barns to keep new-born animals warm, and for the quick drying of hay. The greater compactness and decreased fire risk will give them considerable advantage over present types of equipment. Ultra-violet rays are known to have certain well-marked physiological effects, as in activating sterols to produce vitamin D and in keeping in check the growth in length of plants. For producing well-proportioned plants in greenhouses, the use of a new kind of incandescent lamp is suggested which has a globe permeable to ultra-violet as well as to visible rays.

With these and other lamps in proper proportions, a close approximation to natural sunlight can be obtained with control of duration and intensity not possible under natural conditions. The well-known germicidal effects of ultra-violet rays still await a number of possible practical applications on the farm. They may be used, for example, in dairies and stable buildings, as they now are in hospitals to keep down the germ population of the air. They may be called on to control the spread of epidemics among farm animals, and to check the growth of moulds and other fungi on hay, grain and other products. Their fluorescent effects may aid in diagnosing animal diseases and in examining vegetables and fruits. With Dr. Buttolph, physicist of the General Electric Company, Mr. Porter is publishing some of his suggestions in *Agricultural Engineering*.

Helium Production in the United States

THE developments of the last twenty years in helium production in the United States are described in *Engineering* of January 26. Reference is made to a lecture delivered recently in the College of Engineering of the University of Maryland by Dr. C. W. Siebel, supervising engineer of the Government-owned helium plant near Amarillo, Texas, and to a memorandum issued by the United States Bureau of Mines. The present helium-producing plant at Amarillo has a capacity of 24 million cubic feet of helium of 98·2 per cent purity a year, but it is stated in the Bureau of Mines memorandum that, by installing another production unit in existing buildings, the output could be raised to 36 million cubic feet a year. As the present military and commercial requirements, aggregating approximately 6 million cubic ft. a year, are met by operating the plant at about one quarter of the installed capacity, there is a large reserve for emergencies.

In addition to the Amarillo installation, the U.S. Government owns two smaller helium plants, at Dexter, Kansas, and at Thatcher, Colorado; these are not being worked. They were built by private interests and purchased by the Government in 1937. To supply the Armarillo plant with helium-bearing natural gas, the Bureau of Mines has purchased all gas rights in 50,000 acres of land comprising the Cliffside gas field. It is stated that, on the basis of a conservative estimate, the Cliffside area contains at least 100,000 million cubic feet of natural gas having a helium content of 1·8 per cent. This is equivalent to a reserve of 1,800 million cubic feet of helium, or approximately two hundred times the average annual production during the last ten years. In addition to the resources at Cliffside, the U.S. Government possesses two helium reserves in Utah, which are being retained for future needs.

Mineral Resources of the British Empire

DURING the War of 1914–18 a Royal Commission formed the conclusion that an Empire Development Board was desirable, and there the project has been allowed to rest. An editorial article in *Sands, Clays and Minerals* (autumn issue, 1939) urges that no time should be lost in an intensive survey of the mineral resources of the Empire. The War, so far from causing a postponement of such a survey, should hasten it, and the survey must be carried out from a national point of view regardless of the possible financial profit that may accrue from the mining of any mineral. We cannot afford to wait while commercial interests debate the potential profit in a new venture: access to new supplies of a mineral ore may be vital to victory. The writer makes it clear that he is not thinking in terms of politicians and their methods of control. In that direction he foresees no hope of initiative. If anything is to be done, technologists will have to get together and do it for themselves.

It is proposed that the scientific men of Great Britain should draw up a scheme of Empire development, communicate it to corresponding groups in the Dominions and Colonies, and then give the plan such publicity that even the dead hand of the politician could not destroy it, and possibly some public-spirited men might launch the venture free from the shackles of official control. Emphasis is laid on the conception of a just minerals policy for the Empire in the peace that is to come, the necessity for preventing the exploitation of resources falling to the wrong kind of private enterprise in which profits are the one consideration, and finally the desirability of making the Empire's mineral resources available to all.

An Artificial Mastoid for Audiphone Measurements

THE *Bell Laboratories Record* of November 1939 contains a paper on the development of bone-conduction audiphone receivers by M. S. Hawley, of the Transmission Instruments Engineering Department of the Laboratories. To provide a method of measuring the response of bone conduction receivers under the correct mastoid load, an artificial mastoid was developed. The impedance offered by the mastoid to a bone conduction receiver was measured on a number of people and then a rubber block was designed that presented to a receiver placed upon it approximately the same impedance as the average human mastoid. Since the artificial mastoid is based on average values of mastoid impedance, there may be slight variations in the results obtained with it and with some particular subject. The possible deviations are indicated by a diagram, which shows responses obtained with the artificial mastoid and with one particular subject. At very low frequencies here is an evident slight departure, but over the major part of the frequency range the results are in close agreement. Measurements on the same instruments made over a period of a year have shown very good correlation. Eventually the rubber pad ages and its impedance changes. The replacement of the old pad by a new one is a simple matter, so that the ageing of the rubber pad is not of much consequence. The artificial mastoid may be used in making other tests on receivers in which it is desired that the receiver be coupled to an impedance load equal to that of the head. Such tests include electrical impedance measurements, rattle tests, and non-linear distortion measurements.

Earth Tremor in New Jersey

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has now determined the epicentre of the earthquake of November 14, 1939, to have been near lat. 39° 45′ N., long. 75° 18′ W., which is only 10′ due south of the point suggested as being very near to the epicentre by the Franklin Institute at Philadelphia. The depth of focus is estimated as having been about 25 km.

We are indebted to Prof. William A. Lynch, of Fordham University, New York, for the information that in the summer of 1938 a series of local shocks occurred to the north-east of the above epicentre in the region of lat. 40° 8′ N., long. 74° 32′ W., the two most severe of which were on August 23 at 3h. 36m. and 7h. 3m. G.M.T. On the basis of a canvass of volunteer correspondents and observers, the Coast and Geodetic Survey then announced that the intensity of these "apparently did not exceed V according to the Modified Mercalli Scale of 1931" (felt by nearly everyone; many awakened; some dishes, windows, etc., broken; a few instances of cracked plaster, etc.). The earth tremor was not strong enough to be registered on the seismographs at Kew Observatory. "Earthquake History of the United States", part 1 (1938), published by the Survey, lists only four moderately strong earthquakes for New Jersey up to the year 1936. In our previous note on the earthquake (NATURE, Nov. 25, 1939, p. 904) New Jersey was wrongly stated to be one of the New England States.

Central European Observer

WHEN the Czech nation lost its independence in 1620 its cultural life ceased. Yet Comenius and other teachers continued their educational work in exile. To-day, the nation is again under foreign domination, its universities and scientific institutions are closed and its cultural publications no longer appear in the country itself. One has, however, resumed publication in London. From 1923 until the end of 1938, there appeared in Prague the *Central European Observer*, a review in English dealing with science, art, literature and industry and with European affairs generally. In common with other Czech cultural reviews, it suspended publication after the virtual loss of independence in 1938. It is now appearing again as a fortnightly journal "to study, as it had done in Prague, the problems of the Danubian basin with special attention to the peaceful collaboration of peoples inhabiting it, in the new Europe which must arise from the present cataclysm".

The *Central European Observer* was always well informed on scientific as well as other matters, and gave readable accounts of archæological, biological, chemical, physical and other scientific discoveries and advances made in Central Europe, and its industrial sections frequently referred to new technical applications of scientific knowledge. The first issue of the new series, which retains most of the features of the former *Central European Observer*, contains an article by the late Karel Čapek entitled "The Death of Archimedes".

American University Education

A DECEMBER number of *School and Society* opens with "Statistics of Registration in American Universities and Colleges, 1939", a remarkable survey by the president of the University of Cincinnati. No fewer than 648 institutions are noticed with various comments in detail, and one realizes the vast attendance in a population, perhaps, four times as big as that of Great Britain. The figures, 873,697 full-time students, and with part-time and summer schools, 1,323,874, show an advance on 1938. The United States spends more of its holidays in learning than Great Britain does, though some of the instruction provided and degrees awarded do not reach the British level of attainment. The south-central divisions of East and West and teachers' colleges and technological institutions show the largest increase. In the Freshman Table the trend of the time appears in the 34 per cent additions to engineering, and we are glad to see a distinct though lesser gain in liberal arts. The establishment of a Graduate School of Education at Los Angeles may in time modify the crudities of American films and scenario writers.

Whales

UNDER the title of "Whales, Giants of the Sea", Mr. R. Kellogg contributes to the *National Geographic Magazine* of January a long article on whales and whaling which is specially noteworthy for the detailed notes on the size, appearance, distribution and habits of more than thirty species of cetaceans and coloured illustrations of nearly every species. Each illustration depicts the whale at sea, often feeding, sometimes in contact with its enemy and frequently in schools. These pictures probably constitute a unique gallery and are of considerable value.

Society for the Bibliography of Natural History

AT the annual general meeting of the Society for the Bibliography of Natural History held on February 3, the following officers for 1940 were elected: *President*, Dr. C. Davies Sherborn; *Treasurer*, Mr. Francis Hemming; *Secretary*, Mr. Francis J. Griffin. The Treasurer's report indicated that the Society's financial position is strong; but the need for new members was stressed if the Society is to continue its activities on the present scale. It was reported that a fund has been set up for the publication of facsimiles of rare works, and the president, Dr. C. Davies Sherborn, has started the fund with a handsome donation.

Aftershocks of the Earthquake in Turkey

THESE still continue in considerable numbers and some reach a high intensity. In the Erzinjan area the two villages of Besin and Pulur were destroyed by a shock which killed forty-five people and injured many more on February 3. On February 4, tremors were felt at Ankara, Sivas and Zara, and a village was destroyed, killing ten people and seriously injuring three others.

The Colonial Service: Recent Appointments

THE following appointments and promotions have recently been made in the Colonial Service: M. Halcrow, agricultural officer, Kenya, agricultural officer, St. Helena; T. D. Marsh, agriculturist, senior agriculturist, Malaya; F. R. Mason, deputy director of agriculture and fisheries, director of agriculture and fisheries, Palestine; R. Smeathers, assistant conservator, Tanganyika Territory, assistant conservator, Trinidad; T. G. Wood, senior assistant conservator, conservator, Nigeria; R. Coulthard, veterinary officer, senior veterinary officer, Nigeria; R. M. Gambles, veterinary research officer, Palestine, veterinary officer, Cyprus; D. R. R. Burt, lecturer and head of Department of Zoology, professor of zoology, University College, Ceylon.

Announcements

THE Harben Gold Medal for 1940 of the Royal Institute of Public Health and Hygiene has been awarded to Sir Leonard Hill, formerly professor of physiology in the University of London. The Smith Award for 1940 has been conferred on Sir William Savage, formerly medical officer of health, Somerset.

AT a meeting of the Royal Astronomical Society held on February 9, the following officers were elected for 1940–41: *President*, Prof. H. C. Plummer; *Vice-Presidents*, Prof. David Brunt, Prof. Alfred Fowler, Dr. H. Spencer Jones, Sir James Jeans; *Treasurer*, Mr. J. H. Reynolds; *Secretaries*, Dr. R. d'E. Atkinson, Mr. D. H. Sadler; *Foreign Secretary*, Sir Arthur Eddington.

THE annual prize awarded by the Royal Asiatic Society for its universities prize essay has been awarded this year to Mr. Asa Briggs, of Sidney Sussex College, Cambridge. Of the subjects offered, Mr. Briggs wrote on "The Influence of Sea Power on the History of the East India Company".

THE Sixth International Congress for Experimental Cytology, which had been arranged to take place in Stockholm during July 25–August 1, 1940, has, on account of the international situation, been postponed indefinitely.

PROF. BIDHAN CHUNDER ROY, of Calcutta, has been elected president of the Medical Council of India in succession to Major-General E. W. C. Bradfield. Prof. Roy is the first non-official president and the first Indian to hold the office.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 267. CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Anthropological Nomenclature

ANYONE who has followed the revelation of new knowledge on Pithecanthropus and Pekin man by Weidenreich and von Koenigswald in the columns of NATURE and elsewhere during recent months cannot but agree with the opinions expressed by Prof. Le Gros Clark[1]. If the usual rules of nomenclature are to be followed, the generic name Sinanthropus must now be regarded as a synonym of Pithecanthropus.

Prof. Le Gros Clark's letter raises once more the whole question of nomenclature in physical anthropology. To put the matter briefly, the naming of the forms of recent and fossil man is in a chaotic state, and the misuse of the term 'race' in anthropological literature has long been a matter for adverse comment. Several ineffectual attempts have been made to rectify matters, most of them over-enthusiastic; for example, those of Sergi[2] (1908) and of Pycraft[3] (1925).

To be consistent, the same general principles should be adopted as in dealing with other zoological groups. Differences within the family Hominidæ may be of three or more orders, and in assessing the value of physical (including morphological, physiological, serological) differences the following general principles should be followed.

(1) *Generic* differences involve differences in external or internal anatomical structure. Examples: the differences between a lion (Panthera) and a cat (Felis), or those separating Pithecanthropus from Homo.

(2) *Specific* differences involve no differences in structure. They include differences in bodily proportions (total size or relative differences in appendages); differences in bodily form; constant major differences in coat pattern, or the distribution of pigment in skin and hair. Specific characters are not necessarily associated with geographical range. Examples: the differences between lions and tigers, or between Negroes and Mongoloids.

(3) *Subspecific* (syn. racial or geographic variational) differences are those occurring between the members of a widely distributed species, and are correlated with climatic and other geographic factors, although experimental removal to other localities proves the characters to be usually fixed. Subspecific differences include differences in colour and texture of pelage; variations in length of coat, or of its special peculiarities (manes, crests, etc.) and minor differences in pigmentary pattern. Examples: the differences between the lions of Asia and those of Africa, or between, say, American Indians and typical Mongoloids.

It is essential that the term 'race' in anthropology be synonymized with 'subspecies', and used for no other purpose. By so doing considerable confusion at present existing will disappear. Groups of Hominids of lesser rank than subspecies should be designated 'peoples' (*populi*), and this term should likewise be restricted to this usage. Linguistic differences should on no account be utilized alone in physical anthropological diagnosis, though they may carry weight as confirmatory evidence.

Mutants are not synonymous with subspecies, though they may be subspecies in the making. Commonly but single individuals or small family groups (for example, of albinos) are concerned, but sometimes, as in certain lower Primates, whole colonies of mutants occupy certain localities to the exclusion of the normal form. Where a particular mutation is common, it may affect all the subspecies of a given species (for example, partial albinism in the monkey *Kasi senex* in Ceylon).

Interspecific hybridism is unusual, though not unknown in Nature. It is commoner under domestication, hence frequent in Homo, the most completely domesticated of all animals. Fertility of the hybrids will depend on chromosomal compatibility or the reverse.

Intersubspecific hybridism is the rule where two subspecies meet in Nature, as on the geographic frontiers, where intermediate types are usually found. Chromosomal incompatibility is lacking; if it were not, the differences would be of specific rank. Geographic separation is normally the only barrier to complete commingling of subspecies, with the consequent swamping of the differences; but in man, artificial barriers, such as caste, constitute additional factors tending to isolate breeding groups.

It remains to apply the above generalizations to the members of the family Hominidæ, both recent and fossil. There seems to be no dissenting voice to the generic separation of Pithecanthropus and Pekin man from other Hominids, but most anthropologists lump all or nearly all the remaining forms under Homo, and even under a single species thereof. It is manifest that, if the above principles are observed, the Neanderthaloids at least require generic separation, and this has already been suggested by some, the name Palæanthropus Bonarelli being available.

Most isolated new discoveries of fossil man are automatically placed under Homo and labelled with a specific name based on the locality of the discovery. This procedure has been very loosely carried out in the past, without waiting for complete examination of the specimen or comparison of its status with known forms. It is generally merely to serve as a label for description of the specimen. For example, we have *Homo modjokertensis*, which, with advancing knowledge, proved to be a juvenile Pithecanthropus, and *H. kanamensis*, based on a mandibular fragment.

On the other hand, many anthropologists, disregarding the rules of nomenclature, relegate all forms of Homo that do not differ structurally from what they loosely term 'modern man' to the sole species *Homo sapiens*, irrespective of geological age, geographical distribution or differences of a specific order.

The problem of the conspecificity of all living humanity has always been a thorny one. Allowing, however, for modern concepts of the status and limits of 'species', there is no reason to assume, as was once done, that acceptance of several species of living Homo necessarily implies a polygenic origin. If we are to be consistent and adhere to the general principles enunciated above, it is impossible to escape the view that there are several 'species' of living man, and several more fossil kinds. Moreover, some, if not all, these species have evolved geographical variants requiring trinomial nomenclature.

Many changes will be required if the above argument is to be acted upon, and new definitions will have to be prepared in certain cases. There will, no doubt, be plenty of scope for differences of opinion, but in any event the adoption of this or some similar scheme will assist in smoothing out considerable confusion. Space forbids the discussion of any details here, but one point that particularly comes to mind is the necessity of restricting the term *Homo sapiens* either to 'white man'—in which case Mediterranean, Alpine, etc., will become subspecies of it—or to some particular group of Europeans.

Scope and Limitations of Physical Anthropology

RECENT statements regarding physical anthropology are full of interest, but they omit the practical issue, which is the definition of a standard. During 1917–18, I was a medical officer employed in Egypt to assess the physical and mental capacity of soldiers, and decide who should be put into front line service and who should be employed in supporting services and in what capacity.

The story of national efficiency soon revealed itself. It is set out in a work of mine called "A Vision of the Possible". Some soldiers saw sufficiently well with glasses, some had some defective hearing on one side, and some had a varicose vein. I did not regard the vast majority of these as physically deficient, and, with the exception of those who had some ear disease, I could not see how anything could have been done to prevent these conditions. A vast number had bad teeth and were relegated at once to a large number of dentists stationed close to the front line, and were duly attended to.

In this respect I think something could be done in the way of national prevention. I believe I am correct in stating that the predynastic Egyptians, the original Hawaiian and Maories and the uncivilized (if it is justifiable to use such a term) Australian aborigines all had good teeth. The recent publication of the elaborate uncultivated diet of the Australian aborigine explains why he lived and thrived where civilized man died of starvation. But the Pharaohs suffered from dental disease, and so do the other races named, since contact with Europeans and different foods.

In the course of my work I realized that if the defects mentioned were regarded as barriers, there would be a sadly depleted army, and I am grateful that the commander-in-chief, Lord Allenby, endorsed this view and our action.

In the course of an investigation made long since, Lang and I found that in most wild animals refractive errors were not common, though certainly met with in some of the marsupials which have almost rudimentary eyes. But gross errors of myopia, hypermetropia and astigmatism were met with in many domesticated animals.

It is more than evident that Le Gros Clark, Mellanby and others have a powerful case for inquiry on the broadest basis possible, for the problem is not simple. But I conclude by stating that if you reject one man for refractive error, another for defect in one ear and so on, you get an utterly false standard of physical efficiency, and for that reason the usual figures given for rejection from the army never make any serious impression on me, as I think they do not express the common sense of the problem.

Blood Groups of the Angami Nagas

REFERENCE has been made in NATURE[1] to the report of the British Association Research Committee on Blood Groups among Primitive Peoples. The blood group percentages of the Angami Nagas, based on 96 tests, are given as follows:

O	*A*	*B*	*AB*
35·4	34·4	25·0	5·2

These differ greatly from those on the same people published by Capt. Mitra[2], which are as follow:

O	*A*	*B*	*AB*
46·06	38·78	11·52	3·64

The percentage of *B* given in the British Association data is thus more than double that published by Capt. Mitra and there is also an appreciable difference in blood group *O*. It is also stated in the British Association report that the blood group results accord with the view of Mr. J. P. Mills that the Konyaks are more primitive than the Angami-Rengmas, but if Capt. Mitra's Angami Naga results are compared with those of the British Association on the Konyaks, they appear to be closely similar. They are as follows:

	No.	*O*	*A*	*B*	*AB*
Angami (Mitra)	165	46·06	38·78	11·52	3·64
Konyak (B.A.)	127	45·7	40·2	10·2	3·9

The British Association results, however, confirm the predominance of *A* over *B* in this region excepting among the Thado-Kukis, which I also had pointed out in my recent paper on "Blood Grouping Investigations in India, with special reference to Santal Perganas, Bihar"[3].

Coprophagy in the Wild Rabbit

REPORTS of recent experiments by Madsen[1] and Eden[2] have shown refection to be a normal physiological process in the laboratory rabbit. A few observations collected by me, while studying the ecology and population dynamics of the wild rabbit, suggest that this process also occurs in natural conditions. From Eden's experiments, 54–82 per cent of fæces passed are shown to be normally refected, the advantage of the process to the rabbit being equivalent to "chewing the cud". It is possible that there is a further ecological advantage, which operates under wild conditions.

The population studied by me was that of a warren near Oxford, and a little more than 50 per cent of them were trapped during 1939 and marked in the ear with numbered celluloid disks, so that observations could be made from a neighbouring 'hide' and the individuals and sexes identified by means of a telescope.

Most of these observations (March 1939 to date) were made in the late afternoon, the time when wild rabbits become active and come out to feed. Generally the period of feeding activity is preceded by about half an hour, in which some, at any rate, of the inhabitants are sitting about basking or cleaning themselves. About a hundred observations (15–60 minutes) have been made to date at this hour. Another period of feeding activity is during the late night and early morning, and this is often followed by quite a long period of basking and cleaning, especially in sunny weather, though only about 5 per cent of the population remain to do this, as contrasted with 33 per cent, which is the average proportion observed feeding. About thirty morning observations have been made. In addition, about twelve observations have been made in the early afternoon during the winter. Rabbits may exceptionally feed and bask at this time, according to weather conditions.

In all these observations refection has been observed on four occasions, three times in the early morning and once in the early afternoon. It may seem curious after noting the high proportion of total fæces refected in Eden's experiments, that this was not observed more frequently; but in the first place it evidently occurs largely at night, and secondly most of it probably occurs in the burrows. It may in fact only happen rarely above ground, so that a long series of observations, such as these, is needed to record it at all. It is clear from the observations that little, if any, coprophagy takes place in the evening, even when basking and lying out occur, and that the morning is the more usual time. This is to be expected from the rhythm demonstrated by Madsen. The one afternoon observation may have been due to exceptional weather conditions (see below).

The method of taking the fæcal pellets was not the same in every case, and the rhythm also varied. One doe was watched at 7 a.m. in August; she extended one hind leg, lifted up the foreleg and bent the head straight down. Another doe, watched at the same time, in September, leaned over on one flank and bent the head round and down outside both forelegs. A third, a buck, watched at 2.30 p.m. in December, did the same as the latter without leaning over on the flank. The two does took pellets at the rate of one every 5 seconds for about 45 seconds, while the buck watched in the afternoon took them at the rate of one every 30 seconds for 3 minutes. 'One pellet' may, of course, mean a group of pellets evacuated simultaneously. The fourth instance watched was at another warren too far away for details to be made out well.

The afternoon observation was made during very cold weather, when the ground was frozen and food difficult to obtain. In this way the rabbit's coprophagy may well be of ecological importance, enabling it to do without a supply of fresh food for certain periods. I examined three rabbits, which had lain up in a bury for at least three days (the length of time traps had been set at the entrances) and in each case the stomach contained a small amount of brownish material very different in appearance from a fresh grass meal. This almost certainly consisted of fæcal pellets broken up. They must have been taken some hours before, since they showed none of the usual 'stomach pellet' shape or discreteness well known to me from examination of normal live rabbit stomachs.

Thus during difficult periods or when scared into 'lying up' during trapping operations, the rabbit may increase the degree of refection. It would be interesting in this connexion to have counts of normal diurnal pellets produced under different environmental conditions. The ability of the rabbit to lie up for as much as a week at a time in unfavourable conditions is remarkable and is an important factor in forming policies of extermination. The degree to which refection is bound up with this ability is also important and deserves further attention.

Growth Behaviour of Plants following Seed Treatment by Organic Mercury Compounds

ALBINISM in citrus seedlings is not uncommon. Frost[1] suggests that its frequent production by some parents may be due primarily to heterozygosis for various genes for albinism, and perhaps to the presence of unstable genes such as occur in cases of variegation in other plants.

Successful control of seedling albinism in citrus has been achieved in Palestine[2] by treating the seeds in a 1 : 1,000 solution of 'Uspulun' or 'Ceresan' in water.

In this connexion, Perlberger and Reichert[3] state that albinism can also be controlled by dipping the seeds in salt solutions of other metals, including lead, copper, cobalt and nickel. From this they argue that albinism in citrus is a constitutional property inherent in the plant, which manifests itself only at germination and is probably due to a disturbance of the enzymatic systems of the plant at this stage. This is borne out by the fact that salts of heavy metals which are known to have an effect on enzymatic systems cause citrus seeds to produce normal seedlings.

An alternative explanation, however, may possibly be found in a recent communication by Kostoff[4] reporting the induction of atypical growth and chromosome doubling in Gramineæ after treatment with the fungicide 'Granosan' (ethyl mercury chloride). It is conceivable that control of albinism is associated with the induction of abnormal mitosis as the result of seed treatment by organic mercury salts.

The beneficial effects in respect of germination and freedom from seed-borne diseases following the treatment of seed by organic mercury dusts are well known.

Some curiosity has been expressed at the high yields thus obtained with cotton[5], and the opinion has also been advanced that a factor other than the control of seed-borne disease must have entered into the effect.

It would undoubtedly be of interest and importance to investigate this matter more closely in order to determine the correct explanation of these phenomena.

Identity of the Bacterium Causing Potato Blackleg

As a result of the comparative study of Leach[1], the blackleg disease of potatoes is now generally ascribed to *Bacterium carotovorum*, which is also responsible for the soft rots of many of our vegetables and other plants. Previous investigators[2,3,4,5] had described and named slightly different organisms which Leach endeavoured to show were either identical with or at most variants of *B. carotovorum*. This conclusion was based mainly upon four sets of observations recorded by himself or by others: (1) the similarity of the reactions in dextrose, sucrose and lactose; (2) the proved pathogenesis of authentic strains of *B. carotovorum* when inoculated into potato stems; (3) the isolation of this organism from a soft rotted tuber; (4) the blackening of "potato tissue killed by almost any organism" (Leach).

Lacey[6], however, had shown that the organism isolated from blackleg potato plants produced acid and gas in maltose, a sugar not used by Leach, whereas authentic strains of *B. carotovorum* did not, and furthermore, the latter when inoculated into potato stems produced a white pith rot, but never the characteristic blackening of the cortex caused by the former. Lacey considered these were sufficient reasons for retaining the original name of the organism, namely, *Bacillus phytophthorus* Appel. Bonde[7] has recently investigated the soft rots of the potato tuber in the United States and, following Leach, ascribes most of these to *B. carotovorum* (*Erwinia carotovora* of U.S. nomenclature). Like Leach, Bonde did not include maltose among the sugar reactions investigated but worked only with the same three used by Leach. In his tabulated results Bonde indicates that, while the organisms isolated from blackleg produced the characteristic blackening when inoculated into potato stems, some of those isolated from naturally rotted tubers did not.

During the past summer, I commenced a re-investigation of the disease, mainly with the object of trying to ascertain how it is propagated. From blackleg plants collected in various parts of Great Britain and sent to Cambridge for examination by the courtesy of the Ministry of Agriculture and Fisheries, an organism has been isolated which behaves in the manner described by Lacey, that is, produces acid and gas in maltose and the characteristic blackening of the tissues when inoculated into stems of living potato plants. At the same time a soft-rotting organism isolated from carrots was used for comparative studies, the results of which confirm those of Lacey, as it produced only wilting upon inoculation and formed no acid in maltose. It seems certain, therefore, that the organism isolated from blackleg is not identical with what is generally accepted as *B. carotovorum*, in that the former differs in pathogenesis and in an important biochemical character.

The blackleg organism must, therefore, be given a special label, for while it is correct to state that it will reproduce the disease upon artificial inoculation and forms acid and gas in maltose, this is not true of *all* strains of *B. carotovorum*. It is considered that the differences are good specific characters and that the original specific name should be employed, modified to conform with the generic name Bacterium. Appel's original name was *Bacillus phytophthorus*, but the genus Bacillus can no longer be used for non-sporing rods (Resolution I(*e*) approved by the Second International Congress for Microbiology, London, 1936[8]), and I[9] have stated my reasons for using the generic name Bacterium for the soft-rotting bacteria which are closely allied to the colon-typhoid group and for which this generic name is employed by Topley and Wilson[10]. The name of the blackleg organism should therefore be *Bacterium phytophthorum* (Appel) n. comb.

To sum up, blackleg is caused by a specific organism, *B. phytophthorum*, which also produces a soft rot in potato tubers and other plant tissues. Another and distinct organism, *B. carotovorum*, produces a similar rot in tubers, etc., but not blackleg of potato stems. The former produces acid in maltose, the latter does not. Potato tubers found in a rotted condition may harbour one or both organisms.

Listeria: Change of Name for a Genus of Bacteria

I HAVE been informed that at the Third International Congress for Microbiologists, held in New York City, September 2–9, 1939, it was reported to the Committee on Nomenclature that the name *Listerella*, which I proposed for a genus of bacteria in 1927, had already been given to a Mycetozoan by Jahn in 1906.

My proposed name therefore becomes a homonym, but as the genus has acquired some importance in both human and veterinary pathology and references to "Listerellosis" are becoming fairly common in literature, I think that a name as near to my original proposal as possible is desirable. I therefore propose *Listeria* as the name for the genus of bacteria as defined by me in Publication No. 20 of the South African Institute for Medical Research, "The Plague Problem in South Africa", by J. A. Mitchell, J. H. Harvey Pirie and A. Ingram (Whole vol. 3, p. 169).

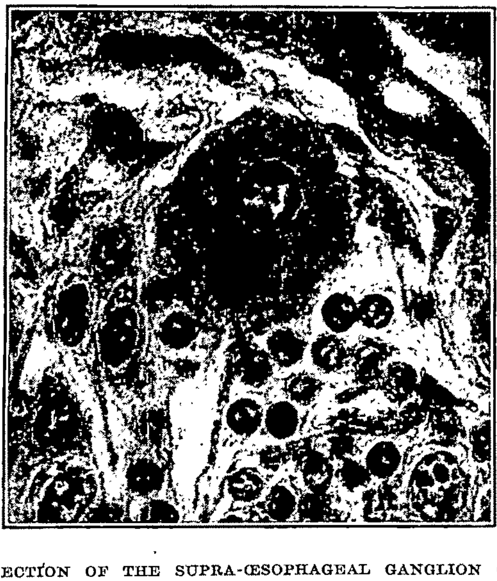
Neurosecretory Cells in the Ganglia of Lepidoptera

FOR many years the investigators of metamorphosis in the Lepidoptera have maintained that the source of the moulting hormone is the brain rather than the corpora allata, which Wigglesworth[1] formerly considered to be the organs producing the secretion in the bug, Rhodnius. Recently, however, Wigglesworth[2] has produced evidence which suggests that an area in the pars intercerebralis of the supra-œsophageal ganglion of Rhodnius is responsible for the production of the moulting hormone. As he points out, Hanström[3] had already described modified nerve cells in this same region which are considered, on morphological grounds, to be probably secretory in function. Neurosecretory cells have been described in several other insects, but it has been reported that, in spite of careful search, no such cells could be found in the brain of the moth larvæ (*Ephestia kuehniella*) studied by Schrader[4].



SECTION OF THE SUPRA-ŒSOPHAGEAL GANGLION OF THE MOTH *Eacles imperialis* DRU., SHOWING LARGE FUCHSINOPHIL CELL WHICH IS CONSIDERED TO BE SECRETORY IN FUNCTION. BOUIN FIXATION, GOLD IMPREGNATION FOLLOWED BY MALLORY'S TRIPLE. PHOTOMICROGRAPH × c. 700.

It seems of interest, therefore, to be able to report the discovery of cells very similar to those described by Hanström which I have found in the ganglia of certain Lepidoptera. They have been demonstrated in the pars intercerebralis of the supra-œsophageal ganglion of adult moths, in larvæ of all instars, and in pupæ. They have been found occasionally in the sub-œsophageal ganglia of larvæ, and in certain of the abdominal ganglia, but not in all. These cells have essentially the same staining properties as those of Rhodnius, being apparently modified ganglion cells, from which they differ in containing a granular cytoplasm or a number of droplets which are intensely fuchsinophil. They are well differentiated by Mallory's Triple strain.

They have been most studied in the larvæ of the moth *Ceratomia catalpæ* Bdv. (Sphingidæ), in which they are generally scattered singly, but may be grouped as those of Rhodnius. Although they may vary in number and in their exact position from larva to larva, no indication has been found of a cyclical production of secretion.

Similar cells have been found in the brains of several species of Heterocera belonging to the families Citheroniidæ, Phycitidæ, and Saturniidæ.

In view of the above-mentioned experimental evidence, it seems possible that these cells are the source of the moulting hormone in the moths, but the fact that similar cells can be demonstrated in some abdominal ganglia indicates that further experimental work must be done before a function can definitely be assigned to them. However, the similarity in staining properties of the cells from the brain and the abdominal ganglia does not, of course, necessarily indicate identity of function.

Zoological Nomenclature

PROPOSAL of a 'stereotyped' zoological nomenclature almost invariably comes from a non-systematist or from a systematist working sporadically on a restricted group in a field where there is but a small literature and few workers. Any active worker in a large and progressive systematic field would realize at once that any 'stereotyping' plan is impossible. In my own subject, ichthyology, there is no general world monograph suitable for 'stereotyping' subsequent to Günther's "Catalogue" (1859–1870), and Günther's classification and nomenclature are now so out of date that no ichthyologist would accept it. There are a number of large faunal works of more recent date, but if they were 'stereotyped' for particular regions, their nomenclatural differences would force the wide utilization of different generic or specific names in different regions for identical genera or species. The vast number of forms thus affected would preclude any sensible arbitration of the conflicts. Not long ago one eminent anatomist proposed that the vagaries of elasmobranch nomenclature be settled by a return to the 1838 nomenclature of Müller and Henle's "Plagiostomen". But he did not suggest what was to be done with the numerous genera and species described since that time and with the various subsequent segregates of Müller and Henle's genera. As a matter of fact, return to this nomenclature of 1838 would necessitate the change of more valid names than were contained in the whole of Müller and Henle's work!

Those systematists who sincerely study zoological nomenclature in an effort to find a way of avoiding vexatious changes usually reach the conclusion that Linnean binomial nomenclature will never be entirely stable, since it is firmly wedded to classification and no one can prevent ideas of classification from changing so long as systematic research is carried on. If absolute stability is imperative, we must cast the entire Linnean system overboard. In my opinion, this will never be done.

As a matter of fact, the particular situation which has troubled Prof. Garstang[1] and Dr. Crossland[2] is not due to the Rules, but to what I consider misuse of the Rules by a small group of Australian nomenclaturists. The nomenclatural *tour de force* to which this group has treated conchology, ornithology, ichthyology, and other fields is deplored by most of the systematists of Europe, America and especially Australia. I am familiar only with the ichthyological side, but in regard to this I can say that comparatively few of these Australian innovations hold water systematically, and many are directly contrary to the Rules. Very likely Prof. Garstang's strictures, if applied to British nudibranchs *in conjunction with full knowledge and correct interpretation of the International Rules*, would restore at least some of the old nomenclature.

I say, at least some. A blind condemnation based purely on personal nomenclatural prejudice is unworthy of consideration in view of the long labours of the many persons who have built up the present International Rules in an attempt to evolve some universal basis for the greatest possible nomenclatural stability in all animal groups. Some general system of rules is imperative, and we have such a system. A great many of the cataclysmic nomenclatural revolutions that occur now and then in restricted groups are due to the utterly irresponsible and capricious nomenclatural practices of past workers. When at last a new and more able generation of workers, cognizant of the importance of adopting a universally acceptable nomenclature, appears, old names by the dozens are likely to fall and older workers to protest bitterly. The latter sometimes fail to realize that they are possibly at fault, or that their particular nook might perhaps need some change in order to make way for a more universal practice.

The present International Rules are not perfect. They have been arrived at only through an enormous amount of work and compromise. How great that work has been, and how difficult it is to obtain agreement on sensible amendments and to prevent the enactment of senseless ones, at the International Zoological Congresses, is largely unknown except to those who have studied the history of the Rules or who have actually been present at the nomenclatural sessions. Some idea of the complexity of points of view that had to be compromised may be gained by reading Dr. Stejneger's paper, "A Chapter in the History of Zoological Nomenclature"[3], and I recommend it to anyone wishing to amend the Rules. But certain improvements might be made without any change in the Rules. Nearly every systematist with whom I have discussed the matter has agreed that the creation of a number of sub-commissions for various animal groups, whose decisions should be subject to reversal only by the main International Commission, would speed up nomenclatural decisions enormously and remove any present causes for dissatisfaction. With several of my colleagues, I hope to present a plan of this sort formally in the near future.

Barkhausen-Kurz Oscillations with Positive Ions

Kownacki and Ratcliffe[1] have previously described an experimental method of investigating electron inertia effects in thermionic vacuum tubes. By replacing the electrons in a triode by positive ions of cæsium, of mass 25×10^4 times greater, they were able to slow down the effective transit times involved by a factor of about 500. In this way they demonstrated the occurrence of rectification effects, dependent upon a resonant transit time, at a wave-length of about 500 metres.

We have now found that it is possible to maintain oscillations of the Barkhausen-Kurz type by using positive ions emanating from a filament. A cylindrical electrode valve of the Type *AT* 40 had some cæsium inserted, and was kept at a temperature of about 30–70° C. with an accelerating potential of the order of 200 volts on the grid and with the anode at zero potential, or at a slightly retarding potential. Under certain conditions of positive ion current, determined by bulb temperature, the valve was found to maintain oscillations with a wave-length of the order of 500 m., corresponding to the time of transit of ions between the electrodes. We satisfied ourselves that the triode alone, with no external circuit tuned to a wave-length greater than about 50 cm. (the natural wave-length of the wire leads), would maintain an oscillation with a wave-length of about 500 m., and the wave-length depended on the electrode potentials employed. The addition of an external tuned circuit greatly increased the amplitude of the oscillation, but had only a second order effect on the frequency. There seems no doubt that the frequency of the oscillations was determined inside the valve itself. Oscillations of this type have often been called true Barkhausen-Kurz oscillations, in contrast to Gill-Morrell oscillations, the frequency of which is mainly determined by an external circuit.

This is not the place to describe our results in detail, but they may be summarized by saying that, at zero D.C. plate potential and with the minimum space current required for oscillation maintenance, the oscillation gave a pure heterodyne note corresponding to a single oscillation with a period approximately equal to one half the time T of ion transit from filament to plate and back, as given by the Scheibe expression[2]:

$$T = 4r_g \left\{ f\left(\sqrt{\log_e \frac{r_g}{r_f}}\right) + g\left(\sqrt{\log_e \frac{r_p}{r_g}}\right) \right\} \Big/ \sqrt{\frac{2eV_g}{M}}$$

Here T is the transit time in seconds, r_f, r_g and r_p are the radii of the filament, grid and plate respectively, V_g is the grid potential in E.M.U., e/M is the specific ionic charge in E.M.U./gm., and f, g are functions given in Scheibe's paper[2]. "Resonance rectification" effects were observed at periods of about T, $T/2$ and $T/3$.

As the space current was increased, the period of the oscillation became increasingly smaller than $T/2$. At a critical space current the type of oscillation suddenly changed, and the single oscillation was replaced by a set of oscillations of slightly different frequencies, which gave an impure heterodyne note. With further increased current the frequencies of the multiple oscillations diverged, and when the condition of space-charge-limited emission was approached, there was an abrupt change to a single oscillation period of rather less than T.

It appears that much information concerning the mechanism of electronic oscillations might be obtained by applying this method of investigation to valves with different electrode structures, and preferably to valves with structures which can be altered without opening up the tube.

Optical Anisotropy of Cellulose Sheet

THE birefringence[1] of 'Cellophane' (regenerated cellulose sheet) has been measured for more than two hundred samples, kindly supplied by the makers. Three main points have emerged:

(1) The birefringence (B) varies with the wavelength of the light used, the law being approximately

$$B = B_0\ (1 - 0{\cdot}000016\ \lambda),$$

where λ is in angstroms.

(2) Results for the birefringence of the thinnest material (about one thousandth of an inch) vary from 0·0056 to 0·0132, with a concentration around 0·0089. The thicker materials (1·2 and 1·6 thousandths of an inch) give, on the average, lower values of birefringence.

(3) The birefringence is least in the middle of the web, and is about 30 per cent greater near the selvedges.

Kornerupine from Ceylon: a New Occurrence

SOME years ago we discovered specimens of kornerupine in mixed parcels of typical cut Ceylon gem-stones, and this prompted us to search for the mineral in gem gravel concentrates kindly sent to us direct from Ceylon by Mr. Hans Van Starrex. From the first lot of rough so examined, which consisted mostly of green zircons, two small pieces of kornerupine were recovered, so that yet another species must be added to the already long list of gem minerals found in the Ceylon gravels.

These two specimens, greenish-brown in colour and weighing 0·430 gm. and 0·436 gm. respectively, have the following properties: density, 3·33; refractive indexes, α 1·671, β 1·683, γ 1·684; $2V$, 25°, $r < v$; α light brown, β yellow, γ dark green. It may be noted that Madagascan kornerupine differs in having r greater than v.

Credit for the identification of our specimens is due to Dr. L. J. Spencer, and confirmation was provided by Dr. G. F. Claringbull, who kindly carried out X-ray measurements.

It is hoped that later a fuller account, together with a complete analysis, will be published in the *Mineralogical Magazine*.

Blue Rocksalt

SPECIMENS of natural rocksalt are frequently coloured, the more usual colours being blue, violet and pink. Blue halite from Stassfurt in particular has received much attention, and many suggestions have been offered to account for the tint. Siedentopf's[1] theory that the colour is due to colloidal sodium was regarded generally as satisfactory until Spezia[2] pointed out that its solution should then be more alkaline than that of the colourless form—which it is not. Doelter[3] regards the colour as caused by foreign inclusions, colloidal or otherwise, and favours a mixture of iron and manganese, though sulphur and organic substances are not ruled out.

More recently, however, Kennard, Howell and Yaeckel[4] have decided against any pigmental theory, as the result of a spectroscopic examination of a specimen of colourless Stassfurt rocksalt containing a distinct zone of blue. No difference in composition between the coloured and colourless parts could be detected; traces of several foreign elements, including aluminium, lithium, silicon and titanium, were present in both. The authors regard their results as supporting the views of those earlier investigators[5] who have attributed the colour to some structural cause.

Apparently, however, gold has not been specially looked for; it may easily escape detection spectroscopically because it is not one of the very sensitive elements, some 10 p.p.m. being the lower limit of detection by ordinary methods. The *Glimmschicht* procedure, developed by Goldschmidt and his co-workers, is claimed to be some fifty times more sensitive[6], but does not appear to have come as yet into general use amongst mineralogists.

We have already shown[7] that sufficient gold is present in the blue and reddish-brown translucent celestines from Yate, Glos., to impart the observed colour if the metal is present in the colloid state. It occurred to us, therefore, that possibly blue Stassfurt halite might likewise contain colloidal gold. This appeared possible for two reasons. First, it is known that sea water frequently contains gold and if, during evaporation, this became concentrated locally, it might easily, if reduced to the colloid state, give rise to coloured streaks in the resulting rock salt. Experiment shows that, under favourable conditions, 1 to 4 p.p.m. of colloidal gold suffice to give a decided tint to a crystal although gold chloride would not, in general, be perceptible.

Secondly, Przibram[8] has noted the analogy between the blue tints of halite and anhydrite. Through the kindness of Mr. Arthur Russell, president of the Mineralogical Society, we have been able to examine a blue-tinted specimen of anhydrite from Cropwell Bishop, Notts., and find it to contain 4 p.p.m. of gold, amply sufficient to yield the observed tint.

Messrs. Gregory and Bottley generously gave us some deep blue Stassfurt halite and in it we found an average of 23 p.p.m. of gold, using an *o*-di-anisidine method[9]. This was again amply sufficient to impart the observed colour. We have found gold to be present also in specimens of both blue and pink halite from other localities, including Hallstadt and Wieliczka (Cracow).

Though we hesitate to draw definite conclusions from a mere half dozen analyses, we do venture to suggest, as worthy of consideration, the view that the colour of halite may, in certain cases at any rate, be connected with its gold content.

Points from Foregoing Letters

W. C. O. Hill shows that differences within the family Hominidæ are of three orders—generic, specific and subspecific. Brief specifications of the status of these are given, but it is pointed out that the members of the family are particularly liable to interspecific and intersubspecific hybridism. Nevertheless, a plea for the observance of the same rules of nomenclature as employed by zoologists is made, and an effort thus made to remove some of the confusion at present existing in anthropological literature. The misuse of the term 'race' and the irregular usage of the title *Homo sapiens* are particularly to be regretted.

Although coprophagy has recently been shown to be a normal physiological process in the laboratory rabbit, there are apparently no previous records of it occurring in the wild. Observations by H. N. Southern of a wild population have shown several instances of refection, and the process is probably important in enabling wild rabbits to tide over unfavourable periods, when food supply is short, or when they are kept in their burrows by persecution.

The slightly differing bacteria causing potato blackleg, the first of which was called *Bacillus phytophthorus*, are now considered to be identical with *Bacterium carotovorum*. One organism isolated from blackleg, however, forms acid in maltose and reproduces the characteristic symptoms of the disease upon inoculation, whereas authentic strains of *B. carotovorum* do not. These differences are considered by W. J. Dowson to be sound specific characters, and necessitate a separate name for this blackleg pathogen. As *Bacillus* can no longer be used, the correct name should be *Bacterium phytophthorum*. Both organisms may occur in naturally rotted tubers.

M. F. Day describes modified nerve cells from the ganglia of several species of moths, and suggests that these may be the source of the moulting hormone in these insects.

G. S. Myers discusses the difficulties of rigid application of the International Rules of Zoological Nomenclature. In order to hasten the procedure, he suggests the formation of sub-commissions for various animal groups, the decisions of which would be subject to reversal only by the International Commission itself.

'Barkhausen-Kurz' oscillations have been obtained by W. S. Elliott and J. A. Ratcliffe at a wave-length of 500 m. by the use of heavy positive ions in place of electrons in a cylindrical triode. The production of oscillations did not require the presence of any tuned external circuit, and the frequency was determined solely by the operating conditions of the triode. The Scheibe transit time formula was obeyed in the case of weak oscillations. Various types of oscillation have been found for different operating conditions.

The birefringence of regenerated cellulose sheet is found by R. C. Gray to decrease slightly with increasing wave-length, to vary within wide limits about a mean value of about 0·0089, and to be, at the selvedges of the web, about 30 per cent greater than at the middle of the web.

Small pieces of the rare mineral kornerupine have been recovered from samples of Ceylon gem gravel, an occurrence not hitherto reported. Optical data for these specimens are given by B. W. Anderson and C. J. Payne.

Blue Stassfurt halite has been found by J. N. Friend and J. P. Allchin to contain gold which, if in colloidal condition, would be ample to cause the observed colour. It is suggested that the colours of various rocksalts may be connected with their gold contents.

RESEARCH ITEMS

Coloured Families in Liverpool

AN investigation undertaken under the auspices of the Liverpool Association for the Welfare of Coloured People into the economic status of 225 coloured families, supplements an investigation made some ten years ago, while reflecting changes in conditions which have taken place in that period ("The Economic Status of Coloured Families in the Port of Liverpool". The University Press of Liverpool, 1939. Pp. 23. 1*s*. net). The investigation was organized and directed by D. Caradog Jones, the material collected and analysed by Kathleen Johnstone of the Department of Social Science in the University of Liverpool. The coloured families investigated belonged to the class of those who had made "domicile of choice", and were known to have been insured under the Unemployment Insurance Acts. The bulk, but not all, of the men were West African in origin. Only one had been in the country for less than five years, while the largest proportion, 100, had been here for more than twenty and less than thirty years. The investigation in the main was confined to householders. Of the families visited, 201 had a married man as head, 2 with a widower, 3 with a single man, and 19 with a widow as head. Of the 206 male heads, 4 were old age pensioners or invalids; of the remainder 149 were unemployed. There are relatively few of pensionable age. There is a high proportion between 45 and 65, with a low proportion between 21 and 45 years. The mean number of children per family is 2·6 as compared with white 4·8. During the last ten years a change for the worse in economic conditions has taken place. Of coloured only 40 per cent were in receipt of earnings as contrasted with 75 of a survey sample of white seamen, while 73 per cent of the coloured were in receipt of unemployment benefit as against 34 per cent white. In relation to the poverty line, the figures are as follow: more than 50 per cent above, coloured 14·4, white 48·5; within 10 per cent above or below, coloured 22·3, white 10·0; and 10 per cent to 33 per cent below, coloured 20·4, white 15·4.

Marriage Customs among the Barolong, South Africa

THE Barolong belong to the western cluster of the Sotho group of the Bantu-speaking tribes of South Africa and are found mainly in British Bechuanaland. Their marriage customs have been studied by Z. K. Matthews on information collected in the course of two visits in 1935 and 1937 (*Africa*, 13, 1; 1940). Socially the Barolong are divided into four sections, named after sons of a former chief who died about 1760. A number of agencies of acculturation, especially missionary influence and administration, have been at work among them. Traditional forms of social grouping based on kinship, locality, age, occupation and rank persist among them, but are undergoing much change. The traditional marriage customs of the Tshidi Barolong attach a great deal of importance to the institution, which is regarded as a state which should not be lightly entered upon, not only in the interests of the individual, but also of their kinship groups, including both the living and the dead, as well as the welfare of the tribe in which they live. It is a sacred duty to one's family to marry in order to continue the line of descent. Much litigation is concerned with family law, and constantly directs the attention of members of the tribe to the importance of the institution of marriage. Marriage is also regarded as a means of cementing friendship between two groups. It is therefore not surprising to find that parents claim and exercise the right to control the marriages of their children, especially when it is a matter of the chief wife, whose children receive first preference in the matter of succession to property. The term 'parents' includes other kinsmen who have the right to advise, especially father's father and brothers and important paternal kinsmen, while the views of the maternal relatives must be taken into account, especially those of the mother's brother, as no serious step can be taken in the affairs of her sister's children unless he be consulted. It must not be taken, however, that the wishes of the man or woman about to be married will be entirely ignored, or that an individual could be compelled to marry against his or her wishes.

Nitrogen Excretion and Metamorphosis

THE generalization that ammonia, urea and uric acid excretion are characteristic of aquatic, amphibian and terrestrial life respectively has received support by the work of A. F. Munroe (*Biochem. J.*, 33, 1957; 1939). He finds that a rapid change-over from ammonia to urea excretion occurs in the tadpole during the metamorphic stage of development, and this is also accompanied by a large increase in liver arginase. The initiation of the change is coincident with the period when the gills are shrivelling and the forelimbs are just piercing the gill coverings and thus giving rise to a functionally active terrestrial animal. He considers that liberation of thyroid substance, the stimulus for metamorphic change, exerts a direct effect on nitrogen metabolism in the liver, and he intends to continue the experiments on axolotls fed with thyroid.

Wing Dimorphism in a Dipterous Insect

JEAN GUIBÉ has published a detailed study of the growth and biology of the fly *Apterina pedestris* Meig., belonging to the family Sphæroceridæ or Borboridæ (*Suppléments* (No. 26) au *Bulletin Biologique de France et de la Belgique*). The most important part of this memoir concerns his breeding experiments. The only known wild type of the insect is the micropterous form, which is widely distributed in the northern Palæarctic region. Three types have been bred out, and it is shown that their inheritance is along simple Mendelian lines. One type, the homozygous micropterous form, produces, *inter se*, its own and no other form. The heterozygous micropterous type produces its own and a macropterous type in approximately the proportion of 3 : 1; in one breeding experiment the progeny resulted in exactly that proportion, namely, 555 micropterous individuals and 185 of the macropterous kind. By crossing heterozygous micropterous forms with macropterous forms, almost equal numbers of both resulted in the progeny. It is evident that micropterism is dominant and that macropterism is recessive. The author concludes that macropterism corresponds to a simple Mendelian mutation, but this idea seems contrary to Dollo's law, since it implies re-acquisition of the former fully winged state. Few biologists will dispute that the original ancestors were fully winged or macropterous at an earlier stage in evolution. It would, therefore, seem reasonable to dissent from the author and interpret the micropterous form as the mutant and the long-winged form as the persistent original type. A further point of great interest is displayed in the author's account of the morphological differences in the wings and venation of the homozygous and heterozygous short-winged forms.

The Genus Streptocarpus

W. J. C. LAWRENCE has reviewed the origins and horticultural development of the genus Streptocarpus in a recent paper (*J. Roy. Hort. Soc.*, **65**, Pt. 1; January 1940). Plants of this group, though now florally valuable in many parts of the world, have been introduced to cultivation from South Africa, where they are concentrated on the Drakensberg Mountains. Stemless species which comprise the section Eu-Streptocarpus vary from the single-leaved forms, which are found mainly in the north, to the rosette kinds, which occur most commonly in the south. Intermediate forms appear in the middle of the Drakensberg range, and since all species of Streptocarpus have the same number of chromosomes, and many readily hybridize, it would seem that they are variants from some common stock. Mr. Lawrence then shows the effect of this variation upon the production of the beautiful garden hybrids now extant. A tetraploid form of a hybrid with *S. grandis* has occurred and has been named 'Merton Giant'. This geographical and genetical analysis of species in the making is a constructive replacement of the tendency to name each inconstant variable, so often favoured by the taxonomic 'splitter'.

Cirque Formation

THE *Bergschrund* hypothesis of cirque formation by a process of basal sapping of the rock has been more or less accepted in one form or another since it was suggested by W. D. Johnson. In recent years, however, W. V. Lewis has stressed the importance of meltwater in cirque formation, and he returns to this subject in an article in the *Geographical Review* of January. The evidence is obtained from cirques in Iceland, Spitsbergen and Switzerland. That meltwater occurs below the level of the *Bergschrund* and melts its way under the glacier seems to be established, but unless this water can refreeze it can have no plucking action on the rock wall. Various observations have shown that low winter temperatures do not penetrate very deep in glaciers, but in the want of contrary evidence Mr. Lewis suggests that freeze–thaw processes do take place at depths below the deepest *Bergschrund*. He points out that no temperatures have yet been taken at the head wall under a glacier, and that only a small amount of the meltwater need freeze in order to affect the rock wall, and finally that at great depths the temperatures must be fractionally below freezing point or the ice would melt under the pressure to which it is subjected. The weight of 36 feet of ice is equivalent to one atmosphere, so that the temperature within a glacier must fall at least at the rate of 0·1° C. for every 500 feet in order that the glacier may exist. If local melting due to descending water releases the pressure at a point beneath a glacier, then the meltwater will rapidly fall in temperature, being chilled by the ice, and rapidly freeze. On re-application of the pressure any ice at 0° C. will melt again. Thus an alternation of freeze and thaw is possible.

Structure of the Pacific Basin

ACCORDING to B. Gutenberg (*Science*, **90**, 456–458; Nov. 17, 1939) the movements along the San Andreas fault in California occur in such a way that the eastern (continental) side moves south-eastward relative to the western (Pacific) side. Ch. Tsuboi has also stated that in Japan, along all faults, without exception the continental (western) side is moving southward relative to the Pacific side. In addition, Bailey Willis contends that movements along the major fault in the Philippines occur in the same way, the continental side moving southward relative to the Pacific side. Gutenberg further states that the definite compression-dilatational patterns observed in all earthquakes without regard to their focal depth indicate that in all shocks the processes producing the waves are of the same type of faulting or shearing and cannot be due to a pure explosion or collapse in the interior of the earth. Great earthquakes are common around the Pacific, and all deep focus earthquakes so far accurately determined have originated in the circum-Pacific area. The boundary of the true Pacific basin is outlined by the earthquake epicentres. On the west side it follows the 'Andesite' line, which separates regions of different petrological and chemical composition. The foci of all earthquakes originating deeper than 200 miles have been found close to, and on the continental side of, this boundary. Different types of seismological evidence concur that continental surface layers appear to be missing over the greater part of the Pacific basin, but they are present in small thicknesses near Japan, New Zealand and California. There is also an area with 'continental' structure in the south-eastern part of the Pacific basin, though partially the Arctic basin appears to be of Pacific type.

Nuclear Isomerism in Zinc

IN the radioactive zinc obtained by bombarding zinc with deuterons, two β-emitters of half-lives about 57 min. and 14 hr. have been assigned to the isotope ^{69}Zn, which is therefore a case of nuclear isomerism. J. W. Kennedy, G. T. Seaborg and E. Segrè (*Phys. Rev.*, **56**, 1095) have now shown that the absorption properties of the β-rays from these two activities are the same. The β-spectra are presumably identical, and it is suggested that in each case the β-rays come from the 57-min. product, while the 14-hr. ^{69}Zn is a metastable excited state of the nucleus which decays to 57-min. ^{69}Zn with emission of a γ-ray. The γ-rays of energy 0·47 Mev. should therefore have no correspondence in time with the β-rays. This was verified by a coincidence counter arrangement which in a check experiment successfully detected the coincidences between the β- and γ-rays of thorium B. An attempt to separate the isomers chemically by taking advantage of the γ-ray recoil of the 57-min. product gave no positive result.

PROBLEMS OF EVACUATION

ASPECTS of evacuation problems are discussed in recent articles in the *Political Quarterly* and the *Quarterly Review*, which make a number of useful suggestions for their solution. Reviewing the working and present position of the evacuation scheme in the *Political Quarterly*, Mr. A. D. K. Owen suggests that in Scotland uncertainty concerning the financial aspects of evacuation played a considerable part in deterring many people from going away or permitting their children to leave vulnerable areas. He considers that more effective publicity, directed to the poorer sections of the population, relating to the financial implications of evacuation might have resulted in a more satisfactory response.

While in the reception areas the situation is in many ways not unsatisfactory, it is difficult to see how the evacuation scheme can be successfully rebuilt in the absence of compulsory powers. Mr. Owen suggests that certain districts within the existing evacuation areas should be scheduled as specially dangerous—all places, for example, within a certain distance of military or naval targets, shipbuilding yards, docks or important railway junctions—and children of school age prohibited from living in them save in very exceptional circumstances. He also suggests that the law of school attendance should be amended so as to prevent parents from bringing their children home from reception areas without good reasons.

The first measure would involve transferring all schools serving the prohibited districts to reception areas, and the second would make it possible to plan ahead with some assurance that the population for which plans are being made would not melt away before they matured. Schools in those parts of the evacuation areas which lie outside the prohibited districts should be opened as soon as they have been given reasonable protection, but a fresh approach made to parents in these areas to persuade them to allow their children to be evacuated or re-evacuated.

Capt. Frederic Evans, in the *Quarterly Review*, directs attention rather to measures which might be taken in the reception areas to organize new life for evacuees within the strange environment to which they have been taken. He emphasizes the importance of balancing out school accommodation and staffs, the development of specialized accommodation for difficult children, clinics, recreation and other purposes. Holiday camps, youth hostels, and village halls could all offer important contributions, and if well organized might contribute to a closer wedding of the town to the country, with far-reaching and beneficial consequences to the whole nation.

Psychological and financial problems have to be faced and the careful planning of the medical services in the country is of special importance. Their staffing and provision pre-suppose a national service. Capt. Evans urges that the considerable expenditure involved in the various social services required to solve these problems must be incurred or we may find the War has been fought in vain.

Dr. W. A. Robson's article, "Evacuation, Town Planning and the War", is concerned with the wide issues which are opened up by the evacuation not merely of school children, but also of civil servants, business houses, etc., and the imperative need for some central control and planning if chaos is not to result from the indiscriminate location not merely of industry in the reception areas but also from the tremendous demand for premises and land by the civil and military authorities. The demands of the War Office and the Air Ministry for camps and aerodromes must be met without question or delay; but it would be the gravest mistake to permit all these new and necessary constructions arising from these as well as from civil needs, and also the consequences of evacuation, to take place in utter confusion or on the basis of *laissez-faire*, and with a complete disregard of the peace-time situation which will follow the War.

For this reason, and because our war-time exigencies are strangely consistent with socially desirable peace-time purposes, Dr. Robson views with such alarm the abandonment by the Government of the reports of the Royal Commission on the geographical distribution of the industrial population. Town and country planning should now acquire a new and more important status and be placed in the hands of a strong central department competent not only to deal with the special needs of the Service departments and the Government offices, but also to take over the long overdue task of directing the location of industry and formulating a national plan for the whole country.

AIR CONDITIONING

AN abstract of a paper on "Air Conditioning" read by W. Chambers to the North Midland Section of the Students of the Institution of Electrical Engineers and published in the Institution's *Journal* of December gives a clear account of the objects to be attained by air-conditioning and of the methods by which it can be done.

The object is to maintain in a building an atmosphere that is most beneficial to the health of the occupants or which is most suitable to the process of manufacture carried on therein. To maintain these conditions, it is necessary to control the heat content or temperature, the purity, the moisture content (humidity) and the distribution of the air. A ventilating scheme in which the air is filtered, comfortable in temperature and adequate in volume, is sometimes considered entirely satisfactory, and little if any attention is paid to its moisture content, although the latter has a great effect upon the comfort of the human body.

In the case of public buildings where the number of occupants may be large and the lighting load large in comparison with the human content, the heat and emanations produced by the occupants have to be counteracted. The atmosphere should have a normal natural temperature and moisture content, with sufficient movement of the air to overcome stagnation.

To raise the temperature of the air in winter, it is only necessary to pass it over a hot surface, and most air heaters therefore consist of finned tubes which are steam-heated, and over which the air is forced to pass by means of centrifugal type fans. It must be remembered that heating lowers the relative humidity, owing to the fact that heated air is contained in a larger volume, but it still carries the same initial quantity of moisture as before heating took place. A pre-heated spray washer to maintain the humidity under control is often used.

In summer, in cooling the air the reverse applies, the relative humidity being increased, so that drying is necessary. This is done by exposing the air to cold surfaces or cold spray, whereby excess moisture is condensed and the air left saturated at a lower temperature. This can be done by mixing the air with air which has not been cooled.

In industrial neighbourhoods, it is necessary to extract from the air dust and grime particles. For this purpose filters are used, and the entire volume of air to be circulated is passed through them. Washers, viscous-type filters and throw-away type filters are used. The last type consists of a cheap fabric which may be cleaned by a vacuum cleaner nozzle, but it is more usual to dispense with them entirely and replace by new fabric. The efficiency of these filters is claimed to be greater than 99 per cent with removal of particles down to 1/30,000 in.

The comfort chart which the American Society of Heating and Ventilating Engineers has evolved shows that summer and winter conditions vary and that the average conditions are a temperature of 72° F. with a relative humidity of 50–60 per cent for summer and a temperature of 66° for winter with a similar humidity.

In an actual installation, the air is first passed through a filter and then tempered in a preheater; this has the effect of preventing the incoming air from being too cold and freezing the water in the washer. The science of air-conditioning is making great progress. The engineer of the future who aims at a thorough mastery of his subject must know physics, especially thermodynamics, and have also some knowledge of those branches of chemistry, medicine, biology, psychology and physiology connected with it.

ORIGIN OF THE CORPUS CALLOSUM

IN "Man's Place in Nature", T. H. Huxley expressed some astonishment at the abrupt appearance of a corpus callosum in placental mammals, suggesting that this phenomenon represents "the greatest leap anywhere made by Nature in her brainwork". Later on, between 1887 and 1895, this problem was studied by a number of anatomists, including Osborn, Zuckerkandl, Symington, Herrick and Elliot Smith, and several divergent opinions were expressed as to the phylogenetic origin of the commissure.

The evidence was clarified to a very considerable extent by the detailed work of Elliot Smith, who made full use of his opportunities in Australia for studying the comparative anatomy of monotreme and marsupial brains. Elliot Smith believed the corpus callosum to be a neomorph which is characteristic of eutherian mammals, and he suggested that its development was facilitated by the bilaminar formation of the fornix commissure which is developed in the marsupial brain. This observation also led him to infer the probability of a metatherian ancestry for placental mammals. Elliot Smith further directed attention to the distorting effect of the corpus callosum on the hippocampal formation, whereby the latter becomes stretched out into a thin atrophic layer of grey matter—the indusium. The latter, again, becomes continuous anteriorly with the hippocampal rudiment found in the precommissural area of the cerebral hemisphere. All these observations, and the conclusions whch are to be drawn from them, have been accepted for many years by most comparative neurologists.

Quite recently, however, the whole question has been raised afresh by the contention of an Australian anatomist—Dr. A. A. Abbie[1]—that in its development the corpus callosum does not, after all, make use of a previous pathway already established by the fibres of the dorsal lamina of the fornix commissure, but is an entirely new commissural connexion formed along a zone of fusion between the two cerebral hemispheres which occurs *dorsal* to the hippocampus. According to Abbie's interpretation, the indusium is thus not the rudiment of the hippocampus at all, but a representative of an adjacent cortical area, the subiculum.

In a communication to NATURE[2] Abbie discussed the bearing of his conception of the origin of the corpus callosum on the ancestry of the Eutheria. It is interesting to note, however, that his conclusions do not differ essentially from those inferred by Elliot Smith on other grounds, for Abbie contends that the expansion of the neocortex and the consequent formation of a hippocampal fissure are the minimal requirements for the development of a corpus callosum, and this condition is first realized in the brain of monotremes and marsupials.

But it is important to note that Abbie's interpretation of the development of the corpus callosum has not passed unchallenged. In the current issue of the *Journal of Anatomy* another anatomist in Australia, Prof. F. Golby, has subjected the new thesis to a very critical examination[3]. His observations suggest that Abbie has been misled in his interpretation of microscopic sections by the distortion of the hippocampal formation at the subsplenial flexure, a distortion which has resulted in a reversal and displacement to a dorsal position of some of the fibres of the fornix commissure (forming the fornix superior), as well as in an illusory appearance in the position of the corpus callosum relative to the hippocampus. Moreover, Goldby reproduces what appears to be a very convincing photomicrograph of a sagittal section of the brain of a rat which illustrates the precommissural hippocampal rudiment extending *dorsally* to the genu of the corpus callosum to become directly continuous with the indusium. Other observations of Goldby on the brain of a bat, Eptesicus, in which the disturbing influence of a subsplenial flexure is absent, also indicate that (as Elliot Smith maintained in his classical studies) the corpus callosum of placental mammals really does lie morphologically ventral to the hippocampus or its vestiges.

It remains to be seen whether Dr. Abbie's theory will find acceptance with other comparative neurologists. It may be suggested, in any event, that it will require to be supported by embryological evidence before it is found to be acceptable.

A ROMAN TOWN IN EAST YORKSHIRE

THE completion of five seasons excavation in the Bozzes Field, at Brough, East Yorkshire, affords an opportunity for a summary of the results of the investigation. Although further excavation may necessitate modification of detail, it is considered that the examination of this Roman site has gone sufficiently far to secure the main outlines and conclusions as to its history which have been attempted by Mr. Philip Corder and Rev. Thomas Romans ("Excavations at the Roman Town at Brough, 1937", *Hull Museum Publications*, No. 206; 1939).

Although the site lies within the northern military area and is on a route that was of great strategic importance during the early wars against the Brigantes, its occupation throughout its history, except for a brief period in the first century, was of a civil character. The Parisii of the wolds, in whose territory it was situated, were village dwellers, and no hill-top fort or town is known in the part of Yorkshire which they inhabited. Petuaria, as it is now known the town was called, eventually became the tribal capital and a walled town with Romanized institutions, but in size it never exceeded twelve acres.

Little is known of the life of the Parisii before the Roman conquest, but a settlement has recently come to light at North Ferriby on the north bank of the Humber, placed conveniently on the pre-Roman route across the Humber and at the same time well situated for overseas trade with the Belgae of the Continent, for which evidence is afforded by Samian ware, *terra nigrea* and butt beakers found side by side with native vessels. Occupation, apparently, closes in the middle of the first century, at about the time of, or soon after, the establishment of the Ninth Legion at Lincoln in A.D. 47 and the construction of Ermine Street. North Ferriby was then abandoned and the inhabitants, moving about three miles up the river, founded Petuaria at the point where Ermine Street crosses the Humber.

The phases of occupation may be summarized in brief as follows: The original settlement, little more than a kraal of native huts, without defences or regular plan, was swept away and the sites of the huts levelled to make way for the first Roman town in the opening years of the second century. This town also was without defences. For a period after A.D. 71 a semi-permanent military base camp existed north of the settlement, which was abandoned after the construction of a great permanent fort farther north at Malton. In the reign of Trajan at the turn of the century grandiose plans were initiated for rebuilding the whole town in stone in Roman fashion. Massive foundations were laid and good roads made for the first time. These plans were never carried to completion.

The reason for the interruption, which appears also at Malton, is unknown. Early in the reign of Hadrian, building was resumed, attention being directed first to the defences, for which the earlier plan had made no provision. These defences are contemporary with Hadrian's Wall. The earliest buildings in stone within the town now appear, but their construction is poor and suggests haste. Thirty or forty years later much building activity is evident. In the reign of Antoninus Pius the defences, in which ramparts of turf had been employed, were entirely reconstructed in stone, a massive wall revetment being constructed in front of a rampart of red clay incorporating the earlier turf bank. The Antonine period marks the hey-day of Petuaria, and small though it was, it must have been a centre of Roman culture.

Throughout the third century town life in Britain declined, while large estates and farms flourished. Petuaria shared the general fate. No complete building can be ascribed to this century, though coins and pottery attest a continued occupation. It shared also, however, in the attempt to revive town life in the fourth century under Constantius Chlorus. The town walls received massive rectangular towers, 25 feet wide and 10 feet deep. Within the town old buildings were reconditioned and new ones constructed. The attempt to put new life into the town failed here as elsewhere and beyond a few minor alterations to existing structures no building within the town can be attributed to a later date than the beginning of the fourth century. The coin list dwindles and ends with single coins of Gratian and Magnus Maximus, while late fourth century pottery of the period of the coastal signal stations occurs only sparsely. It is impossible to resist the conclusion that the life of Petuaria had already shrunk to insignificance at the time when the farms of the wolds were still prosperous.

Evidence of the status of Petuaria is afforded by an inscribed stone set up in the reign of Antoninus Pius by M. Ulpius Januarius, *aedile* of the *vicus*, to commemorate work done at his own expense in connexion with a theatre. Normally the *vicus* was unimportant and the business of its council parochial. The existence of an *aedile* at Petuaria implies the dignity of a self-governing *civitas* with full jurisdiction over all the *vici* in its territory. This in conjunction with other evidence would go to show that Petuaria had now become the seat of cantonal authority.

MECHANISM OF DRUG ACTIVITY

"HOW DO DRUGS ACT ?" was the subject of an address delivered by Sir Walter Langdon-Brown to an evening meeting of the Pharmaceutical Society on February 13. He classified the principal ways in which drugs act thus: (1) they increase or diminish the effects of stimuli reaching the cell from without; (2) they modify the chemical changes occurring within the cell itself; (3) they may themselves be so altered in chemical constitution by the cell as to be capable of fresh activity, yet with diminished toxicity. He illustrated each of these methods by examples, some of the best illustrations of the first group from hormones, of the second from vitamins, and of the third from chemotherapy.

It was little realized at the beginning of this century that a new era had dawned when Langley showed that the effect of adrenaline on any part was the same as if the sympathetic nerve to it had been stimulated; it merely seemed an interesting example of a chemical substance imitating a nervous stimulus. But it was much more important than that; although adrenaline has no effect on a structure which has never received a sympathetic innervation, Elliott found that cutting off that innervation did not abolish the effect of adrenaline on a structure which had once possessed it. On the contrary, its effect was actually increased. For this reason both Langley and Elliott independently put forward the theory of a receptive substance beyond the nerve ending, on which the drug acted. Sympathetic stimulation has been found to produce adrenaline at the nerve endings; this is in addition to the adrenaline always stored up in the medulla of the adrenal gland which can be drawn upon as an emergency ration when there is a sudden demand for widespread action of the sympathetic for purposes of defence. Other illustrations were given showing how the normal transmission of the nervous stimulus is effected and the ways in which it may be interfered with or assisted by certain drugs.

Sir Walter next gave some examples of the way in which drugs may act by modifying the chemical changes within the cell itself; he started by discussing some of the activities of thyroid extract, the quickening effect of which on metabolism has been described as the draught to a fire.

Other observations on drugs and oxidation processes were followed by extensive references to vitamin C (ascorbic acid), which is now so widely used as a drug. As a strong reducing agent, it acts by balancing oxidation and reduction changes in the cell. Much study, said Sir Walter, has been recently directed to vague ill-health, short of that necessary to induce scurvy, due to lack of vitamin C. He gave an example which showed clearly that a specific case of vague ill-health was due to dietetic deficiency, and the material ascorbic acid was ready to hand to re-establish healthy oxidation and reduction changes within the cell.

Chemotherapy illustrates the third group, the alteration of a drug by the cell so that it assumes fresh activity yet with diminished toxicity. Sir Walter said that the treatment of any malady with a chemical agent of known composition may be included, strictly speaking, in the term chemotherapy, although it is almost universally limited to the treatment of parasitic diseases by chemical disinfection or control of the causative agent without producing marked toxic effect on its patient. The specific effects of drugs such as emetine in amœbic dysentery and arsphenamine in syphilis depends upon their chemical interactions with some constituent of the living cell.

MILK AND NUTRITION

A FULL account of a large-scale trial of the effects of giving various milk supplements to children at school is given in the final report of the Milk Nutrition Committee ("Milk and Nutrition". Part 4. National Institute for Research in Dairying, Shinfield, Reading. 2*s*. post paid). The researches of the Committee have been undertaken to compare the nutritive values of raw and of pasteurized milk. In the present report, results are given of tests upon school children of the growth and health-promoting properties of supplements of ⅓ or ⅔ pint of milk—amounts the same as those which figure in the Milk-in-Schools Scheme of the Ministry of Health.

Some eight thousand children from five different areas were divided at random into four groups, to receive, over one year, a daily ration at school of (1) biscuits; (2) ⅓ pint of pasteurized milk; (3) ⅔ pint of pasteurized milk; and (4) ⅔ pint of raw milk. The children were periodically examined, measurements being made of their physique together with assessments of their state of nutrition, intellectual ability, and other features such as posture and complexion.

The general trend of the figures obtained, set out in a number of tables, shows that the children given milk supplements increased in height, chest-circumference, and strength of pull to a greater extent than those receiving biscuits, and also improved more in their general state of nutrition and in their teachers' assessment of their ability. In addition, those on the larger milk supplement usually showed an improvement above those on the smaller, while there was no consistent difference between those on similar supplements of raw and of pasteurized milk. The advantages accruing to the milk-drinkers compared with the biscuit-eaters were small, though uniform and significant, amounting to less than $\frac{1}{10}$ in. in height and ¼–1 lb. in weight over the whole year during which the experiment was in progress. There was, unfortunately, no means of control over the home diet, and it is therefore possible that some given biscuits may have received additional milk at home, while milk-drinkers may have had extra biscuits.

A summary of the previously reported results of laboratory experiments on animals and feeding trials on calves is also given in this report.

SEVENTY YEARS AGO

Nature, vol. 1, February 17, 1870

Measurement of Geological Time

The first of two articles by A. Russel Wallace on this subject appears. "Modern geological research has rendered it almost certain that the same causes which produced the various formations with their embedded fossils have continued to act down to the present day." This, Wallace points out, should make it possible to estimate the time represented by the whole series of formations, but the changes observed are too minute and too imperfect for such an estimate to be of value. The gaps in the record might be filled from observation of the changes of animal and plant life presented by each formation. "To measure geological time, therefore, all we require is a trustworthy unit for the change of species : but this is exactly what we have not yet been able to get ; for the whole length of the historical period has not produced the slightest perceptible change in any living thing in a state of nature."

Wallace then gives a summary of astronomical evidence on the subject, referring in considerable detail to Croll's calculation of the eccentricity of the earth's orbit and the precession of the equinoxes in relation to the production of climatic changes. "Mr. Croll considers astronomical causes to be the most important and effective agents in modifying climate while Sir Charles Lyell maintains that the distribution of land and water, with their action on each other by influencing marine and aerial currents, are of preponderating importance."

The Newall Telescope

"The 25-inch Equatorial Telescope, commenced several years ago by T. Cooke and Sons, of York, for R. S. Newall, Esq., of Gateshead, is now so far completed that it has been removed from the works at York into its observatory in Mr. Newall's grounds at Fern Deal. The completion of a telescope with an object glass of 25 inches aperture marks an epoch in astronomy, and its completion in England again places us in the front rank in the matter of the optical art."

The tube of the instrument was 32 ft. long, and cigar-shaped ; it was constructed of steel plates riveted together ; focal length of lens, 29 ft. A full-page wood-cut of the instrument was printed.

Professor Liebig disputes Pasteur's view that the decomposition of sugar in fermentation depends on the development and multiplication of yeast-cells and that fermentation generally is only a phenomenon accompanying the vital process of yeast. He expresses the opinion that Pasteur's researches have not explained fermentation ; but have only made known another phenomenon—the development of yeast—which equally requires explanation.

The *Lancet*, in speaking of the arrangements of hospitals, instances, as much needing reform, the system of grouping together indiscriminately in medical words, cases of various affections, in an atmosphere which may be destructive to some patients while it is suitable to others. Thus we may find lying side by side a case of bronchitis and one of fever ; a patient with phthisis and another with gangrene of the lung.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Headmaster of the Technical School, Oldbury—The Director of Education, County Education Office, County Buildings, Worcester (February 21).

Borough Engineer and Surveyor, Buildings Surveyor and Surveyor to the Local Education Authority—The Town Clerk, Town Hall, Eastbourne (February 29).

Headmaster at the Queen Mary's (Boys) School, Basingstoke—The County Education Officer, The Castle, Winchester (March 1).

Professor of Chemistry—The Registrar, University of Allahabad, Allahabad, India (March 31).

Professor of Physics—The Registrar, University of Allahabad, Allahabad, India (March 31).

Entomologist to the South African Sugar Association—The Director, Sugar Experiment Station, Mount Edgecombe, Natal, South Africa.

Temporary Meteorological Assistants (Male) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

Engineer for the Malayan Postal Service—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9113).

Assistant Engineer for the Drainage and Irrigation Department, Malaya—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9114).

Superintendent Engineer to the South Wellan Internal Drainage Board—Calthrop and Leopold Harvey, Clerks to the Board, Solicitors, Spalding.

Mineralogist or Geo-chemist—The Director of Research, British Pottery Research Association, Queen's Road, Penkhull, Stoke-on-Trent.

SCIENTIFIC MANAGEMENT IN ADMINISTRATION

IN the reviews of the progress of the War which have been given from time to time by the Prime Minister in the House of Commons, the preliminary testing of many of the plans drawn up for the organization of the nation in time of war has been revealed. In these reviews, however, the actions of the armed forces or diplomatic matters have figured largely, and the home front as a whole has scarcely received the attention it merits. Particular aspects have been noticed, but the balanced and critical view of the whole economic effort of the nation, which is one of the main points in the argument for a Ministry of Economic Affairs, has been lacking.

Accordingly a broadsheet on the home front issued by Political and Economic Planning (P E P) a few weeks ago is the more welcome for the careful survey of the position and its constructive criticism of matters on which Government spokesmen have said little or nothing. The first of the subjects reviewed in this broadsheet, that of the higher machinery of Government—the functions of the Supreme War Council and the War Cabinet—has also been touched upon in two admirable articles by Mr. Hugh Quigley and Mr. L. Urwick in successive numbers of *Industry Illustrated*.

The P E P broadsheet, reviewing the establishment of five new ministries for war purposes and the vast new functions of three other departments, points out that the Cabinet secretariat remains the only body concerned with co-ordination over the whole field. While the appointment of Lord Stamp as adviser to a Cabinet Committee on Economic Co-ordination shows a recognition of the importance of planning an economic policy on a much wider basis, the new office in its present form does not constitute an Economic General Staff. Moreover, the development of regionalism in civil defence holds immense implications for a possible peace-time reorganization of our administrative system.

Mr. Quigley's and Mr. Urwick's articles make interesting comment on the question put by P E P, whether the Civil Service can meet the greatest demands made on it since it assumed its present form, and adapt itself to the new conditions with their primary call for decisions and planning. Mr. Quigley, emphasizing the importance of the efficient conduct of industry and of fitting the needs of war to an industrial machine which is allowed to develop normally and with the minimum interruption, makes the point that regulations tend to conceal the need for initiative and bold planning, when in truth more efficient management is needed.

No country appears to have made any serious effort to determine what are good and valuable industrial products in a period of war and what are bad and non-essential. Such knowledge, however, is basic for the efficient use of a country's industrial resources, and this kind of assessment requires the experience and knowledge of those in control of industry. Accordingly, Mr. Quigley urges the importance of bringing management into consultation to ensure the maintenance of the important volume of normal production, and to determine the limits beyond which any strain on industry or any further loss of its man-power would be a source of dangerous weakness.

Mr. Urwick, while endorsing Mr. Quigley's argument as to the support which industry and management could render in maintaining the economic life of Great Britain in a planned and ordered relation to the whole national effort, lays his main stress on the value of the principles and practice of scientific management in solving a whole series of difficulties now facing civil, military or naval authorities. Little progress has yet been made in the application of such principles and practices to the task of government, and Mr. Urwick indicates two directions in which scientific management could give important assistance. The first of these concerns ministerial co-ordination. At the very top, the British Government affords an example of infringement of the vital principle of span of control, according to which no man can co-ordinate effectively the work of more than five subordinates whose work interlocks. He urges that a true War Cabinet of half a dozen senior ministers without departmental responsibilities, giving continuous attention to policy and each responsible for co-ordinating a group of departments dealing with some special aspect of the national effort, is a necessity for the effective conduct of the War. Existing arrangements are technically faulty and therefore fundamentally unworkable.

Mr. Urwick's second suggestion, concerning the assistance which scientific management could give in the training and control of clerical staff in the Army, is illustrative of a number of directions in which the application of modern management principles could be of service in fields where administration generally is probably as efficient or more efficient than in industry. The importance of utilizing such services grows as the field over which control becomes essential is extended, and as the checks on autocracy are weakened through the suspension of municipal or parliamentary elections, or the disappearance of local initiative and radical modification of the whole basis of local government.

To neglect such matters is to court disaster, or at least to imperil the very work upon which we depend for the sustained effort and sacrifices demanded in a protracted struggle. Mistakes have already been made, as in the indefensible commandeering of schools and hotels, which have more seriously damaged the credit of the Government than its spokesmen care to admit. The absence of reform or evidence of contrition in such matters as these has consequences which are not the less serious because they are not immediate, and they may easily sap confidence at the very moment it is most essential.

Criticism in Great Britain of the control already exercised is indeed directed, not against the principle of control, but against the way in which some controls have been effected. The authors of imperfect plans—and the bunglers of good plans—cannot claim immunity from constructive criticism merely because we are at war. On the contrary, the onus lies on those who designed or are administering the controls to say where criticism is not justified. That such criticism has frequently been justified by its results and led to the withdrawal or modification of such schemes as those for the control of fish marketing, war risks insurance, or the Ministry of Information, is one of the most hopeful signs that the Government is not unresponsive to public opinion or unmindful of the necessity of safeguarding the liberty of the subject and inviting the co-operation of the public.

The most serious effect of such errors of judgment as the commandeering of hotels and schools is not the individual hardships involved, or the general irritation at stupid blundering, but the lack of confidence engendered in the smooth working of the vast national plans as a whole. The P E P broadsheet does not, with all its constructive criticism, suggest that there is anything essentially wrong with the principles of our war-time planning, though it indicates details in which criticism and public co-operation might improve matters. It does indicate, however, the existence of conflicting orders and a lack of co-ordinating authority, and the necessity of facing a drastic revision of traditional policies.

These points are specially stressed in relation to finance, to the planning of priorities, of man-power, agricultural policy and food control. All these, moreover, are clearly interlocked. In regard to finance, the war budget relies almost completely on the old system of taxation. The vital issue is to decide how much of the national income can be taken for war purposes, or what combination of price control, inflation, taxation and borrowing should be used for diverting enough of the national income from civil to military needs. One of the most difficult problems of war finance is how to control the dislocating effect of a vast increase in Government expenditure and the consequent widespread distribution of purchasing power at a time when a large proportion of the country's resources—labour, capital equipment and raw materials—is diverted from the provision of goods for current consumption to war purposes. The suggestion recently put forward by Mr. J. M. Keynes for dealing with this question of control of consumption by compulsory saving is a departure from the traditional policy which deserves careful examination, although good results are already being obtained by voluntary effort.

Such questions of finance are linked inextricably with the maintenance of export trade, and the question of exports and the distribution of export effort between the old heavy industries already fully engaged with war work and the newer light industries. It affects questions of prices, wages and profiteering and the planning of priorities. Clearly the Central Priorities Department should be used to plan the whole economic output of Great Britain and not just the supplies of the defence services. The needs of the civil population and of the export trades must also be considered and balanced against each other, if the most efficient use of available resources is to be secured.

Planning the utilization of Great Britain's resources of man-power to the best advantage is the function of the Ministry of Labour in consultation with the Labour Sub-committee of the Ministerial Priorities Committee. There is already evidence that lessons have been learned from the blunders of twenty-five years ago, and the compilation of the National Register should provide information for planning man-power much more comprehensively than before. It is doubtful, however, whether the true value of the Register in the scientific organization of a civilized community is yet realized. The Central Register has already proved its usefulness in placing certain classes of scientific workers where their services are most urgently needed; but it should be remembered that the whole register is experimental, and that experience is likely to suggest many improvements and extensions.

Complex problems of labour are bound to arise not merely in the munitions industry but also in agriculture and through the relations between rail and road transport, where fundamental reconsideration of the positions of both industries is urgently required. In agriculture, itself so closely linked with the question of food supply and rationing, a general clarification of aims is urgently required. Modern industrial, economic and scientific technique finds little reflection in much of the farming still practised; the pooling of all available knowledge in the service of war-time efficiency on the farm is as important as pooling labour, machinery, horses or even the land where the units are now too small to operate economically.

If, however, control and rationing are to be accepted with good grace, there must be confidence that adequate co-ordination of the national effort exists, and that steps have been taken to secure the scientific and impartial utilization of the full resources of the nation in the one purpose that counts. Rationing, whether of petrol or food or other commodities, will be accepted without demur so long as the private user does not feel that he is deprived of supplies for officials to waste. Scientific workers, who have their own contribution to make in so many widely different fields, should not therefore be unmindful of this supreme need for insisting that the fullest use is made of the methods and principles which scientific management puts into our hands, for securing the due co-ordination and efficient operation of any enterprise in the fulfilment of its purposes, whether they be those of a private business or of a nation at war.

THE ORIGIN OF LIFE

Life's Beginning on the Earth

By Prof. R. Beutner. Pp. x + 222. (London: Chapman and Hall, Ltd., 1939.) 12*s*. 6*d*. net.

THE "Manager of the Performance" as Prof. Beutner invites his readers to regard him, apparently supported by the Provost, Dean and staff of his Institute, stands on the stage before the curtains are drawn for the film. The technique is useful in that exact references to literature are unnecessary and concentration of eye and brain is secured. There is also no index and the mind is not usually disturbed by references to the sources from which the pictures are derived. These lapses make the film less useful to scientific men, while causing less strain on the commencing students of science and medicine for whom it is perhaps primarily intended. To these, all comparisons between the reactions of living and non-living matter cannot but present helpful analogies, which may well prove of great value to medicine, as suggested in the epilogue. The subject, however, has a wider appeal, for evidently certain of its sides have been the author's research life for many years. It deserves more than a passing reference.

As a practical presentation we suggest that the manager has reversed the order of the pictures of his film. We would feel greater happiness in leading off with the reactions of the oil drop to its environment in comparison with Amœba, because the layman learns the reactions called 'living' in connexion with tangible analogies that he can the better understand. Beutner, following on the pioneer work of Jennings, studied here, using Telkes drops made from fresh brain material which, of course, is rich in the lipoid lecithin. These are more complex than the drops of vegetable oils, but their method of preparation precludes the idea that they contain living matter. Experimentally they present many varieties of pseudopodia and of movement such as are found in the naked Protozoa[1], but there is never any increase of the mass. They exhibit respiration which in places lowers surface tension. The drops formed from the brain of an exhausted animal no longer show the mass of tiny fibres usual to those from the healthy animal. Poisons such as strychnine inhibit respiration and stop all movement, while, if free access of air is prevented, suffocation follows. No reactions can be recorded in pure water, for the drop is starved. The author next proceeds to a set of analogies in the phenomena of electrical actions in the nerve impulse, Lillie's researches freely quoted. He has studied the electric organs of fish and made artificial fat batteries which yield by analogy helpful results. His experiments suggest to him that poisons *may* kill by interference with the electrical mechanism rather than by their reactions on enzymes.

We pass by the numerous analogies between the actions of living cells compared with those of artificial gelatin cells, the formation of semi-permeable membranes and the magnitude of osmotic pressure. In this matter Traube's research (1860–70) can be read profitably by biologists even to-day, together with its subsequent development by Pfeffer. Leduc's imitations of many living forms are well illustrated, these artificial osmotic structures that counterfeit plant-growths amazingly well. "Salt and water are a part of life itself."

The consideration of the unique nature of carbon and its compounds leads the reader to basal considerations. The chemist, using elaborate technique, can make many carbon compounds that the organism produces with the greatest ease by means of enzymes or ferments. The most widely known is chlorophyll, the utility of which requires no comment. Usually any action necessitates the employment of several enzymes, so that the extraction of some in pure form has had no practical results. To this category perhaps belong the plant-formed vitamins, which in animals must be re-fed to the body continually to avoid disease. Then there are the hormones made inside the body and carried to where they have the highest activating influence, the best known being insulin. To-day, it is within our imagination to transform one of these bodies into a living body as, by radioactivity, elements can be transmuted. Naturally the search is for the smallest living matter and so we are led to the filtrable viruses[2], the disease-producing effects of which are well known. Their actions so closely simulate those of bacteria that life must be allowed to them. From these, crystalline substances were obtained by Stanley in 1935 using tobacco-mosaic leaves, afterwards those of phlox and spinach. These were repeatedly crystallized and found to produce the diseases at will, all facts being reasonably "explained on the assumption that the different virus proteins are in fact the different viruses". The problem for the chemist is to synthesize the enzyme and, this accomplished, to endow it with the property of self-regeneration. On this basis an idea of the development of cells is possible, with all that this entails.

We have omitted reference to the chapter devoted to "vital growth and crystallization" in which, as living matter is made up of diminutive crystals, the building forces are deemed to be similar in the living and non-living world. This leads to Beutner's review of Oparin's work "The Origin of Life", 1938. Condensations of nebular matter from the sun are assumed to produce planets[3], first carbon, then a series of metals, finally water, leaving the atmosphere as we know it; this is in contrast to the planet Jupiter with its methane-ammonia surround. Oparin suggests that organic substances were present in the early ocean as colloidal solutions. The interaction of various colloids caused segregation resembling crystallization, these "coazervates" gradually developing into living organisms. In this process enzymes must have formed in them so that they were able to assimilate substances from their environment. In contrast, Beutner maintains that self-regenerating enzymes formed by electric discharges were the earliest appearance of life—and it necessarily follows that such enzymes may have been formed at all ages in the world's history.

To summarize: research has shown developments of non-living matter strikingly resembling certain features of life, and the further development of such researches may at any moment illuminate the cosmic miracle by which life can only be supposed to have been produced either on this or any other world. J. STANLEY GARDINER.

---

[1] This is perhaps due to liquid crystallization, a process seen in the central filaments of the Heliozoa. The surface covering of Amœba consists of protein and lipoid molecules so that the pseudopodia must be quite different.

[2] Their size is that of the molecule of hæmocyanin.

[3] This view is ascribed to "J. Jeans", who will scarcely desire to be termed "a Russian astronomer". Oparin apparently was not acquainted with Stanley's researches, for they are not included in his bibliography.

SALT DEPOSITS

Steinsalz und Kalisalze: Geologie

Von Prof. Franz Lotz. (Die Wichtigsten Lagerstätten der "Nicht-Erze", Band 3, Teil 1.) Pp. xxvii+936. (Berlin: Gebrüder Borntraeger, 1938.) 84 gold marks.

SALT deposits are of surpassing interest from many and varied aspects. The details of their depositional succession, their complexity and association, and the post-depositional changes which they have undergone provide a vast series of physico-chemical problems which have furnished material for the classic researches of van 't Hoff and a host of others. They are of no less interest to the geologist, who examines in them the record of those rarer episodes in the earth's history when the customary sequence solid-to-solution was reversed. Besides, salt, because of its great chemical and physical reactivity, is the most temperamental of rocks. So soon as it is laid down it is liable to be dissolved, transported, modified by solutions from above or below, and this any number of times. If it is involved in folding of the crust or tectonic events of any kind it reacts like no other rock; instead of folding as other rocks do, it flows, and under continued pressure it may become unstuck from its associates, penetrate higher levels of the crust in intrusive fashion as diapirs and salt plugs and may even flow out on the surface as salt glaciers. Countless surprises are possible if salt deposits are members of a rock series the geological history of which is at all lively.

Lastly, natural salts form one of the most important raw materials of industry. Like other mineral deposits, they are not uniformly distributed among the nations of the earth. In time of war, therefore, certain minerals become "strategic"—as the Americans put it—and of major importance among the strategic minerals are the potash salts. Germany, by virtue of her geographical position in the centre of the dried-up shallow sea of the great salt-building period of the Permo-Trias, has almost a monopoly of potash salts; it should be added that with regard to practically all other strategic minerals her native resources are inconsiderable. It is fitting from the academic point of view that Prof. Franz Lotze, of the University of Berlin, *ein guter Kenner der Salzlagerstätten*, should provide a monograph on the rock-salt and potash salt deposits of the world. It is fitting, too, from many other aspects, that this monograph should now be available at this present time to certain interested, but non-German, parties.

The *Salzband* of this well-known series dealing with the non-metallic mineral deposits is to consist of two parts. The first is the bulky volume under notice here and is concerned entirely with the geological relations of salt deposits. The second part, by Prof. Leonhardt, will provide an account of the mineralogy and petrography of natural salts; the physical chemistry of salt deposition is mentioned only incidentally in the geological part.

Every aspect of the geology of the deposits of sodium and potassium salts of the world is examined in complete detail. The book is divided into two sections. In the first a general geological account is given; in the second special descriptions of the world's salt occurrences are provided. As a start, salt formation at the present day is dealt with, and here is included a good discussion of the origin of the salt in the sea. Halley, as early as 1715, suggested that this was derived from the weathering of the rocks of the continents and thus started a notion which is still current and which, indeed, has formed the basis of one method, now discredited, of estimating the age of the oceans. But the oceanic waters have a content of chlorine far greater than could have been provided by the weathering of primary rocks. It is suggested that whilst the salt of the sea is all derived from primary sources, it has nevertheless arrived in the sea by two routes, the metals from primary igneous rocks, the non-metals from volcanic emanations—the two groups of components are separated by igneous processes but are reunited in sea-salts.

After describing the many types of salt deposits being formed at the present day, Lotze deals with the general geological principles of salt deposition in the past. The relation of salt formation to the great mountain-building periods, the southward migration of the salt-belts during the course of geological time and the origin of *thick* salt deposits are among the topics of interest discussed.

After an account of the secondary changes that salt deposits are liable to undergo so soon as they are laid down—a matter that will presumably be discussed in greater detail in Leonhardt's mineralogical part of the *Salzband*—there follows a full description of the almost fantastic tectonics of salt deposits. The various intrusive, unglued and rootless forms of salt bodies are related to the tectonic styles of the portions of the crust in which they occur. Structural geologists will find here matter of absorbing interest. The first section of this book, that dealing with the general geology of salt deposits, closes with some twenty-one pages of references.

In the second or 'special part' of the volume, detailed descriptions of the salt occurrences of the world are given, the general arrangement being based upon a regional geological foundation. Special attention is directed to the salt deposits of Europe and North America in relation to the large-scale tectonics of these continents. During the War of 1914–18 the virtual monopoly in potash salts possessed by Germany had become forcibly realized by other nations, and consequently there has been, in the post-War period, a strenuous search for new supplies, especially in the United States and the U.S.S.R. Most of the results of these campaigns, especially the Russian, are not readily available, but still Lotze provides a considerable amount of information on non-German occurrences of potash salts. He devotes most space—more than two hundred pages—to the consideration of the immensely important rock-salt and potash salt deposits of the Permo-Triassic basin of Middle Europe, which include the magnificent German potash salt fields and the not inconsiderable rock-salt deposits of the Trias in Great Britain. The elucidation of the various depositional cycles of the German fields, of the facies changes in them and of the palæogeographical conclusions to be drawn therefrom is made particularly clear. Details of national production are not given; these may be found in the current statistical summaries, such as Roush's "Mineral Industry". This 'special part' of Lotze's volume concludes with nearly fifty pages of references.

Fortified with its bibliographical detail, an index of more than a hundred pages, 353 text-figures and numerous tables, this work provides a summary of all that is known about the geology of a group of rocks of outstanding scientific, economic and international importance.

H. H. READ.

THE AMERICAN OUTLOOK ON COTTON

Cotton

History, Species, Varieties, Morphology, Breeding, Culture, Diseases, Marketing and Uses. By Dr. Harry Bates Brown. (McGraw-Hill Publications in the Agricultural Sciences.) Second edition. Pp. xiii + 592. (New York and London: McGraw-Hill Book Co. Inc., 1938.) 30*s*.

IN the enlarged second edition, as in the first, the merits and weaknesses of this book are equally evident. It is a remarkable single-handed production giving the reader a wide view of every part of the cotton field, from the germ cell to the world crop of three million tons. Taxonomy, physiology, agriculture, merchanting, spinning, weaving and statistics are all included. We know of no better comprehensive presentation, and the quality of the citations is such that it can be used as a book of reference.

Its weakness results from the fact that extreme specialization on such a versatile crop as cotton involves the specialist in contacts with every subject under the sun, and in many of these he must be, however unwillingly, a dilettante. Also, he must reside somewhere, and when that residence is in the country which produces half the world-crop of his subject, his presentation must be biased by a tendency to overlook the smaller contributors.

Now, from a cotton-grower's point of view, the United States is mainly a mass-producer of unspecialized raw material, under conditions which as expressed in terms of yield per acre, are also unspecialized. Thus, while America must form the background to any book on cotton, the most advanced and informative work on cotton is nowadays to be found outside it, from countries where small crops present local difficulties, where specialized crops demand special care, or where, as in Lancashire, economic difficulties demand intensive study and research on the industrial end. This widespread area of information outside the United States of America has not been entirely neglected by the author, but it has not been adequately examined. We doubt whether it could be searched and critically sifted single-handed, but the transactions provided by the Shirley Institute in the *Textile Institute Journal* would be expected to provide some of the references in the chapter on cotton-spinning. Similarly, while Egypt is growing her whole crop from pure-line seed under a system of routine seed-renewal, with a yield per acre which is three times that of the United States and a price per pound which is half as big again, some references to Egyptian publications of later date than contributions by the present reviewer published more than twenty-five years ago should surely be of interest.

Substantially our criticism condenses to the title. If this were "Cotton from the American Point of View", we could praise without reserve.

W. L. B.

SOCIAL STUDIES IN ENGINEERING

(1) Spanning-Space
By Claude A. Claremont. ("Science in Action" Series.) Pp. 125. (London: Sir Isaac Pitman and Sons, Ltd., 1939.) 3*s*.

(2) The Development of Power
By Eugene C. Wittick. Pp. xiv+164. (London: Cambridge University Press; Chicago: University of Chicago Press, 1939.) 5*s*. net.

THESE two small books deal with engineering subjects in a popular way, and though their methods of treatment differ, there is a considerable measure of unity of plan to be observed in them.

(1) The first volume is an English publication, one of the "Science in Action" series the purpose of which is to describe, in a readable way, interesting and important activities and the scientific principles underlying them. Here the object is to explain to the general reader the several types of bridges in use and the ideas and principles on which their designs were based. The author, besides being an engineer, is co-principal of the Montessori Training College, London, and has dedicated his book to two small boys. He reasons out, in simple yet graphic language, the fundamental concepts in the design and construction of twelve different kinds of bridge. One could wish that such a book were largely adopted by teachers. The main subject is so familiar both to teacher and child. The historical notes and development, the properties of the materials suitable for each type, and the constructional details make up an impressive picture of purposeful adaptation which must convey a valuable lesson to a child's mind.

(2) In the second volume, the range of the subject is wider. It treats of the several sources of power and describes the machinery used to develop or transmit power in its different forms. The historical notes provide a background which explains and adds interest to later developments. This American publication is intended as a college text-book to stimulate the minds of students and to provide a source of information regarding the influence of this branch of engineering on social life. It may well be imagined that the Egyptian who had roughly devised a wheel which he could turn to raise water more easily than by buckets must have noticed that the flow of the river caused the wheel to turn. By combining the two functions he got a self-operating means of irrigation which left him free for other pressing work. The same simple impulses are at work to-day, though not so obviously, and if such books as these two were generally read and understood, the basic laws operating in our social life would be better appreciated.

A COURSE OF PHYSICAL CHEMISTRY

Kurzes Lehrbuch der physikalischen Chemie
Von Prof. Dr. Karl Jellinek. Heft 1: Grundprinzipien der physikalischen Chemie, Lehre von den reinen Stoffen und Mischungen von Nichtelektrolyten (Physikalisch-chemische Thermodynamik). Pp. xiv+314. 8.50 fl. Heft 2: Elektrochemie Phasenlehre, Lehre von den Phasengrenzflaechen (Kolloidchemie), chemische Kinetik. Pp. xii+292. 7.50 fl. (Deventer: N. V. Uitgevers-Maatschappij Æ. E. Kluwer, 1938, 1939.)

THESE are the first two of four parts of Prof. Jellinek's book, each part being independent. The first part deals with fundamental principles and their application to pure substances and mixtures of non-electrolytes.

The subjects fall under the two main headings of thermodynamics and kinetic theory, and in both cases the subject is fully and clearly treated, all mathematical requirements except the elements of the calculus being explained. There are many worked examples, and this is a very good feature of the book. The diagrams are neat and instructive, although the lettering is sometimes rather small, and there are some useful tables of numerical data. The symbols are well chosen, but a list of them would have been useful. The subjects include Nernst's theorem, which is dealt with from the modern point of view of entropies, and activity as far as it concerns non-electrolytes.

In most cases, alternative proofs of thermodynamic formulæ are given, one based on a cyclic process and the other on the thermodynamic functions, so that the reasoning is always made perfectly clear.

The second part of the book treats of electrochemistry, phase rule, surface and colloid chemistry, and chemical kinetics. The section on electrochemistry deals with electrolytes (including the modern theory of strong electrolytes), electrode potential and galvanic cells, and chemical equilibria with electrolytes (including indicators, heterogeneous equilibria, and fused salts). Although the Debye-Hückel equation is not actually deduced, it is very fully explained and illustrated by examples, and the idea of activity is introduced and used in a very complete and practical manner. The numerical examples frequently interpolated in the text make everything clear and intelligible, and there are many good figures.

The section on the phase rule deals only with one- and two-component systems but comprises well-chosen examples. The treatment of reaction kinetics includes the recent theories of active molecules as well as the classical examples, and the treatment of heterogeneous kinetics is very full, including a discussion of overvoltage and passivity, also comprising modern work.

There is no doubt that this book is likely to prove extremely helpful to both students and teachers, since the author has spared no pains to make the subject clear, understandable, and modern. A good feature is the close relation which is always preserved between theory and practical methods, the latter being explained briefly but adequately. If the remaining volumes of Prof. Jellinek's treatise are as good as these, the complete work will be an excellent survey of modern physical chemistry which will be certain of a warm welcome. The paper and printing are very good, but the number of small misprints is much larger than that included in the short list of errata.

OXFORD MEN OF SCIENCE

Early Science in Oxford
By R. T. Gunther. Vol. 11 : Oxford Colleges and their Men of Science. Pp. xvi+430+50 plates. (Oxford : The Author, The Old Ashmolean, 1937.) 30*s*.

DR. GUNTHER must be praised for the enthusiasm and hard work which have led him in the period between the Wars to found a museum for the history of science in Oxford and to give to science eleven volumes of part of its history. Some of this work has not escaped criticism, but the reception of most of it has been good. The present work is one that deserves a friendly welcome and an accessible place in the libraries of men of science and especially of Oxford men. Dr. Gunther has worked at his task with great energy and purpose, amassing from many sources, many of them little known (unfortunately not listed here), a large amount of interesting information on the personalities, aims and achievements of Oxford men of the past. Dr. Gunther happens to be more attracted to the antiquarian than to any other aspect of the past, to the biological sciences than to the physical, to instruments than to scientific ideas, to museums, perhaps, than to laboratories, and all he writes reflects the man. If we agree to accept Dr. Gunther as he is, and not to expect a cold, impartial historian, we shall have little to criticize and much to praise in this, his eleventh, volume.

The book begins with a survey of the whole subject in lecture form : the inaugural lecture given by the author in 1934 as first reader at Oxford in the history of science. Separate chapters, twenty-one in number, are then devoted to the colleges whose alumni in both the distant and recent pasts have made contributions to science. There is a final chapter on men like Robert Boyle who did scientific work in Oxford independent of the colleges, and there is a gather-up of material, not all of it relevant, in the form of seven appendixes.

In the chapters on the colleges, the worthies of each are presented in turn, their scientific achievements briefly described, and often some odd or out-of-the-way piece of information added ; sometimes a portrait is reproduced. 'Oxford man' is rightly interpreted widely, as anyone of scientific attainments who has been connected with a college, and not necessarily one who had been an undergraduate there. Thus, in the chapter on Merton College we are told of William Harvey, who was not originally an Oxford man, as well as of men like Sir Henry Savile and Grant Allen who were ; Robert Hooke properly comes under Christ Church, although much of his best work was done at the Royal Society in London. If the embrace had been less catholic, Dr. Gunther would have had little to do, for in the far past the number of Oxford men, in the narrow sense of having been undergraduates there, who stayed on after taking their degrees to do great scientific work, could be counted on the fingers of one's hands.

In the descriptions, a little expansiveness on the author's part would occasionally not have been amiss. In the chapter on Oriel College, we are told of the mathematical work of Prof. Baden Powell. Dr. Gunther might have added that Powell, who was elected into the Royal Society so long ago as 1829 and was old enough to have fought at Waterloo, was the father of the present Chief Scout. In the chapter on Christ Church, 'Dr. Tupper' is described simply as an inventor, a D.C.L. and an F.R.S. But he had these six welcome letters after his name before he was thirty-seven years of age, and he was the versifier whose christian name was Martin. Again, V. H. Veley, of University College, is mentioned as having shown that pure nitric acid has no action on copper, but nothing is said of the far greater work of H. B. Dixon, of Balliol, and H. B. Baker, of Christ Church. There was, in fact, at one time in Oxford a school which appeared to set out to show that pure things do not do what it is commonly supposed they do do, one member showing that pure nitric acid does not etch copper, another that carbon will not burn in pure oxygen, a third that pure iron does not rust, and a fourth that pure ammonium chloride does not dissociate thermally. Possibly Dr. Gunther would not regard these investigators as coming into the field of "Early Science".

As was to be expected, this book is well illustrated. The choice has been carefully made and the reproductions are numerous and very good. They include many little-known portraits of Oxford's scientific sons. A. S. R.

AMERICAN VEGETABLES

Vegetable Crops

By Prof. Homer C. Thompson. (McGraw-Hill Publications in the Agricultural Sciences.) Third edition. Pp. xi + 578. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 33*s*.

THIS book is the third edition of a standard American text-book dealing with the production and marketing of vegetables. Particular attention is paid to vegetables cultivated in the eastern States, and all the subtropical products from limited areas of Florida and elsewhere are omitted.

Nine years have elapsed since the previous edition, and opportunity is well taken to bring the text up to date, and to include consideration of recent research, carried out for the greater part at the Cornell Agricultural Experiment Station.

As in previous editions the earlier chapters deal with the principles and methods of cultivation, with soils, manures and fertilizers, and irrigation. A brief consideration of marketing and storage problems is included, but the major portion of the text is devoted to a systematic study of the commoner vegetables.

Although the underlying principles of cultivation do not differ from those laid down in most other countries, the very real differences between local climates and soil conditions, together with differences experienced in transport and marketing, overshadow these similarities. Further complications arise for English readers due to differences in nomenclature, to synonymy, and to different methods of varietal classification. An example or two must suffice: there is no entry in the index of haricot beans, a term applicable to certain varieties of dwarf French beans of which the young pods, but more especially the dried seeds, are so valuable; although the reader will find an alternative classification of beans according to their use, he will yet have to decide whether to include his haricot under snap beans (with edible pods) or dry shell beans. Similarly the classification of cabbages, although based on sound morphological lines, would not be entirely suitable for all our English varieties.

In regard to pests and diseases there are some of major importance in the States which fortunately are not yet with us, but our crops suffer from other pests and diseases which are of such little importance in America that they naturally receive brief attention in these pages; the pests of the potato illustrate this point.

The author includes the deficiency troubles due to a lack of boron, shown in cauliflowers by hollow stems and brown curds, in beet by black spotting, and shown by the brown heart of rutabaga, better known in Britain as swedes.

Although there are brief descriptions of the somewhat uncommon chayote (*Sechium edule*), and okra (*Hibiscus esculentus*) and martynia (as *Proboscidea Jussieudi* Keller) the author omits the yams (*Dioscorea sps.*), the Chinese artichoke (*Stachys tuberifera*), and the Peruvian oca (*Oxalis, crenata*) and other rarer vegetables.

A valuable feature of the book is the literature cited, comprising some five hundred titles, mostly of recent American work. The book appears in the well-known format of the series by the McGraw-Hill Publishing Co., and it is somewhat expensive.

The success of American and British growers in breeding and selecting varieties suitable for their own conditions tends to make this book of somewhat limited use to growers in another country, although its value to students, for whom it is written, is not thereby seriously impaired.

LIVE STOCK POLICY DURING WAR-TIME

BY DR. CHARLES CROWTHER,
PRINCIPAL OF THE HARPER ADAMS AGRICULTURAL COLLEGE

SINCE the eighties of last century, the main effort of British agriculture has been steadily and increasingly diverted from crop growing to the production of live stock and live stock products. According to recent statistics these now account for about two thirds of the total value of the agricultural output of England and Wales, and an even higher fraction of the Scottish output. This expansion of live stock production with a dwindling arable acreage has only been made possible by the import of feeding-stuffs, which has shown a corresponding rise to a level in recent years of about 7¾ million tons per annum. This represents, according to Wright's estimates, in terms of 'starch equivalent' about 22 per cent of the total nutrients consumed by live stock in a normal year (1935), the balance of 78 per cent being obtained from home-produced fodders, roots and corn. In these terms of gross supply, the proportion of imports does not appear to be unreasonable ; but in terms of concentrated foods the balance assumes a very different aspect, since imports are entirely of this class and amount to more than twice the home-grown supply of concentrates. It is inevitable, therefore, that in times of crisis involving shipping difficulties the supply of imported feeding-stuffs, unless vast reserves have previously been accumulated, must rapidly become a serious problem for the live-stock industry, compelling some change of policy, more or less drastic, for the early stages, if not for the whole period, of the crisis.

The general lines along which such adaptation must take place were evolved by force of circumstances during the War of 1914-1918 : increase of home production of arable crops, utilization of household and other food waste, and rationing of available concentrated feeding-stuffs with priority to those classes of animals which either make more economical use of these concentrates or give a product that is of special importance in the national dietary. In the present emergency, therefore, it has been possible from the outset to formulate the war-time policy for the production of live stock and live stock products along these lines, and with varying degrees of grace the broad principle of the policy appears to have been accepted by the industry.

The necessity for the 'speed the plough' and 'dig for victory' campaigns in the interests of the human consumer are obvious ; but both may also be made to contribute substantially to the home supplies of food for live stock, the former through the farm, and the latter through allotments and gardens. A parallel increase must also be effected on our grasslands, where modern research has greatly extended the possibilities of improved management and utilization, and of conservation of surplus produce for winter use. No great expansion of the artificial drying of grass by private enterprise on farms is probable, but serious consideration should be given at once to the possibility of establishing a national grass-drying organization, for which a large nucleus of raw material would be available on aerodromes and other large areas from which the grass needs to be cut and removed periodically through the growing season.

On the majority of farms a corresponding increase in conserved grass supplies would be more readily effected by ensilage, using improved modern methods, and an intensive propaganda directed towards this end ought to be initiated without delay.

By these two methods of conserving young grass, a very substantial reduction in the requirements of ruminant live stock for concentrated foods could be effected, and substantial help thereby given to the solution of the difficult problem of maintaining an adequate head of our non-ruminant stock.

It is on the latter—the pig and the fowl—that the penalty of depleted supplies of concentrates must necessarily fall most heavily, since they can only utilize coarse fodders to a very limited extent, not even sufficient to cover their maintenance requirements, and consequently must depend for the most part upon supplies of grain and meals. According to Wright's estimates of the normal requirements of these classes of live stock under prevailing systems of management, poultry receive 94 per cent, and pigs no less than 97 per cent, of their nutrients (expressed as starch equivalent) in the form of cereals and other concentrates. When these proportions are compared with the corresponding 15–20 per cent for cattle and sheep, and account taken of the paramount importance of maintaining an adequate supply of milk, it is clear that even with drastic changes in systems of management and feeding it will be practically impossible to prevent a considerable fall in the numbers of pigs and poultry. A considerable reduction in the output of pig meat, poultry meat and eggs from the normal sources of home supply can thus scarcely be avoided, although since the best stocks will be retained the fall in output from these sources will not be proportional to the drop in numbers. Greater recourse will also be made by pig and poultry farmers to the feeding of food refuse from hotels and camps, and of grassland and surplus greenstuffs. So far as the use of grass and greenstuff is concerned, however, it is one of the ironies of the situation that the main responsibility for this task of replacing concentrates by greenstuffs should fall upon the two classes of live stock that are least fitted for dealing with large quantities of this bulky, fibrous type of food.

If home supplies of eggs, poultry meat, and pig meat are to be substantially maintained, a new body of producers must be brought into existence, and that is the task now allotted to the cottager, 'back-yarder', and allotment holder. Every household and every vegetable garden produces a certain amount of waste, useless in the house but serviceable as food for small live stock. Such material is generally more easily and completely disposed of through the pig than the fowl, but for most people, especially in suburban areas, pig-keeping will be impossible, and the effort must be concentrated on fowls and rabbits. War-time economy, moreover, will surely reduce the normal volume of household 'scraps' available, and the keeping of even a few fowls or rabbits will only be possible where an organized collection of the scraps from several households can be arranged. In a community properly organized for the purpose, the best plan of all would be for the edible refuse of all kinds to be collected and taken to a communal live stock feeding centre where expert management and proper facilities for the preparation of the food could be provided. Such a centre, with good management, might well be a substantial source of profit to the community.

Before taking up poultry keeping, the 'back-yarder' will be well advised to bear in mind that his household scraps and garden refuse alone will not suffice to maintain his birds in good health and production ; but that he will also need to obtain a quantity of suitable meal, probably at least $\frac{3}{4}$–1 lb. per head weekly. Furthermore he must be prepared to go to a little trouble in boiling or cooking the scraps, as they may be unsuitable or even unsafe in the raw condition. Where garden waste is more abundant than house scraps he would probably be better advised to keep rabbits than poultry, since the rabbit can deal effectively with larger quantities of greenstuffs than the hen, and is generally less fastidious in its appetite for this class of food. Incidentally also, it is perhaps less liable to create a nuisance. German war-time policy for the 'back-yarder' definitely favours the rabbit before the hen, and its possibilities might well receive more attention and publicity in Great Britain than they have yet received.

Whatever class of live stock is favoured, however, it must not be assumed to be a simple matter on which no expert advice is required, and every community in which this class of activity develops should provide an organization through which such help can be readily obtained. There should be no difficulty in any town in forming an advisory panel of experienced men and women, with whom might be associated the adviser on small live stock from the agricultural educational staff of the adjoining county authority. Further assistance is also available in the special leaflets issued by the Ministry of Agriculture and Fisheries.

With all the assistance that may come from the cottager and 'back-yarder', however, the major part of the problem of conserving the greatest possible nucleus of our live stock must lie with the farmer, and must turn upon the efficiency with which our grassland and our reduced supplies of concentrated foods are utilized. There is general agreement that in the interests of children and others for whom milk is almost a vital necessity, and in view of our entire dependence upon home supplies of this commodity, priority in the allocation of feeding-stuffs must be given to milch cows. Beef cattle and sheep are regarded as having the next best claim to consideration, partly because of their relatively low requirement of concentrated feeding-stuffs in proportion to their total food consumption, and partly because of the slowness with which any reduction in our cattle and sheep stocks can be remedied after the War. Poultry and pigs follow without any special discrimination between them in the national policy, although the poultryman may justly claim precedence on grounds of the special nutritive virtues of the egg, through its combination of high nutritive energy with 'protective' factors. From this point of view, indeed, the hen may claim to rank next to the dairy cow in the basic importance of its contribution to the national dietary.

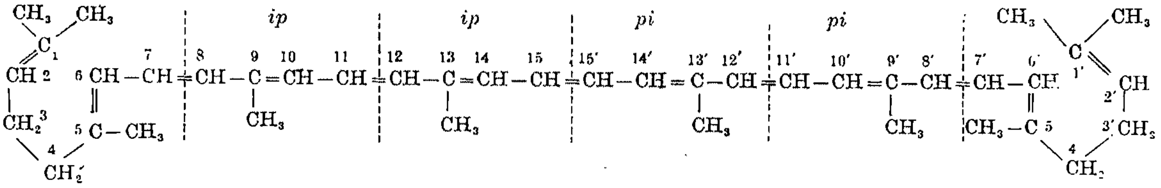
Placed at their present disadvantage in the order of priority, the pig farmer and poultry farmer have clearly the right to insist that every care shall be taken to ensure that the more favoured classes of live stock are efficiently managed, especially as regards their user of imported feeding-stuffs. This can only be effected satisfactorily through an organized scheme of rationing of supplies. Under such a scheme the dairyman, cattleman and sheepman should only receive priority supplies for their surplus production beyond the level that they may reasonably be expected to cover from home-grown supplies of fodder and grain. Furthermore, the total volume of milk and meat production in respect of which priority of foodstuff supply is given should be restricted to the *essential* needs of the public. A volume of milk, for example, that is ample for the needs of infants, adolescents, invalids, etc., must be assured at all costs ; but in view of the serious position in which pig and poultry producers are placed, it is difficult to see why any priority should be given for the production of unlimited supplies of milk for consumption by the adult population.

With the increased arable acreage and intensified utilization of grassland the requirements of the ruminant live stock for imported concentrates should be very substantially reduced, and the pig-man and poultry-man have every right to expect this measure of co-operation from their more favoured fellow farmers.

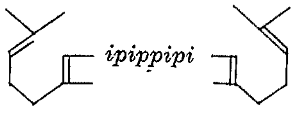
In the case of the poultry-man, and to a smaller degree the pig-man, there are also other weighty considerations that must be taken into account in the development of national policy. A very large section of the poultry industry is in the hands of 'small' people scattered throughout the countryside, whose living and life-savings are entirely bound up with the maintenance of their small enterprises. The welfare of this smallholder element of the agricultural community has always been regarded as being of great importance to the interests of the State, and any ill-considered reversal of this policy, even in war-time, may have grave sociological consequences. Their problem is for the time being extremely difficult, but must receive serious consideration before we can resign ourselves to the inevitability of human sacrifice on the home food production front.

CAROTENE AND ALLIED PIGMENTS*

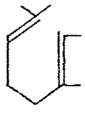
THE simplest carotenoid is lycopene, $C_{40}H_{56}$; on complete hydrogenation to perhydrolycopene, $C_{40}H_{82}$, thirteen bonds disappear. Quantitative degradation by means of ozone, permanganate and chromic acid as oxidizing agents leads to the formula:



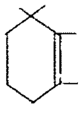
The central polyene chain, C_8–$C_{8'}$ inclusive, is made up of four isoprene units arranged in pairs which are united in reverse order at C_{15} and $C_{15'}$, and may be abbreviated as *ipippipi* (*ip* denoting an isoprene unit). Lycopene may thus be written



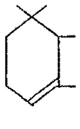
The polyene chain is common to a large number of carotenoids, but the terminal groups may consist of substituted or unsubstituted rings of the α- or β-ionone type as below :



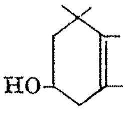
a



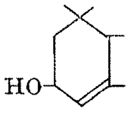
b



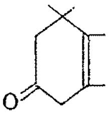
c



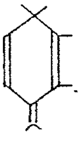
d



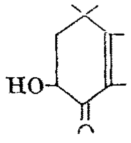
e



f



g



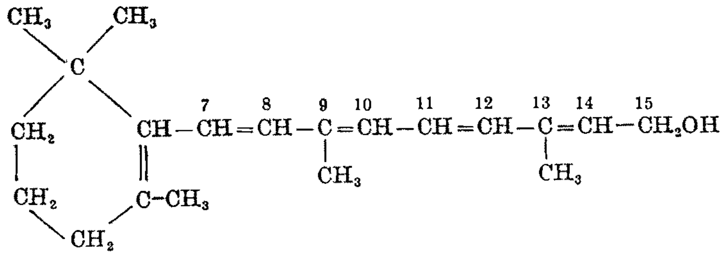
h

Green leaves and other vegetable products contain α- and β-carotene and 'xanthophyll', a mixture of hydroxylated carotenoids, zeaxanthin and lutein predominating. Their functions in plant physiology are not yet understood, but owing to the connexion between carotene and vitamin A, the position concerning the role of carotenoids in the nutrition of animals is much less obscure.

Vitamin A from fish liver oils ($C_{20}H_{29}OH$) possesses a constitution which differs from one half of the symmetrical β-carotene molecule only by the addition of the elements of water:

---

* Based on papers by Dr. R. A. Morton "On the Constitution and Physiological Significance of Carotene and Allied Pigments", and W. M. Seaber, "On the Commercial Determination of Carotene and Allied Pigments with Special Reference to Dried Grass and other Leafy Materials", read at a joint meeting of the Society of Public Analysts and Other Analytical Chemists and the Food Group of the Society of Chemical Industry on February 7.



The fact that green foodstuffs may cure avitaminosis A just as well as fish liver oils was explained when it was found that pure 'carotene' undergoes fission *in vivo* with formation of vitamin A.

The only carotenoids which act as precursors or provitamins A are those which possess intact one half of the β-carotene molecule. They include those shown in the accompanying table, echinonene and a few derivatives prepared *in vitro* from natural provitamins. There is no evidence that animals can synthesize either provitamins A or vitamin A *de novo*, or that the conversion of carotene to vitamin A is reversible.

Substance	Constitution	Occurrence
Lycopene	*a-ipippipi-a*	Ripe tomatoes
* α-Carotene	*b* ,, *c*	Red palm oil, mountain ash berries
* β-Carotene	*b* ,, *b*	Carrots, leaves, etc.
* γ-Carotene	*b* ,, *a*	Leaves of lily-of-the-valley
* Kryptoxanthin	*b* ,, *d*	Yellow maize
Zeaxanthin	*d* ,, *d*	Maize, egg yolk, leaves
Lutein	*d* ,, *e*	Grass, green leaves
* Myxoanthin	*b* ,, *g*	Algæ, especially blue-green algæ
* Aphanin	*b* ,, *f*	
Rubixanthin	*d* ,, *a*	
Astaxanthin	*h* ,, *h*	Crustacea

* Provitamins A.

The animal body contains only small quantities of carotenoids, and is not equipped to assimilate large doses. Carotene utilization is optimal when minimal doses are fed in oil solution, and the transport of carotene through the intestinal wall is conditional on normal fat absorption. The site of the conversion of carotene to vitamin A is generally held to be the liver; certainly the liver is the main storage depot for the vitamin. In most species there is a normal level of concentration of vitamin A—and of carotenoid—in the blood. Carotenoids are also found in the pigmented layer of the eye and in yellow bone marrow.

Milk contains both vitamin A and carotenoids (largely β-carotene) and for a given species the total vitamin A activity of normal milk tends to be fairly constant, but in domesticated animals there are interesting variations with breed. Thus Holstein and Ayrshire cows yield milk with little carotene but more vitamin A, whereas Guernseys give a cream more deeply coloured by carotene but less rich in vitamin A. The new-born possess very low liver reserves of vitamin A, and it is significant that colostrum may possess vitamin A activity one hundred times that of normal milk. Human colostrum is two or three times as potent as early milk, which in turn is five or ten times as rich as the later milk.

The earliest sign of shortage of vitamin A or provitamin A is defective low-intensity vision. Visual purple, the photosensitive substance of the rods, may be obtained from retinas; it is a conjugated protein from which vitamin A can be separated. Faulty dark adaptation is due to delayed regeneration of visual purple, and in the majority of subjects can be remedied by supplementing the diet with vitamin A or carotene. In order to prevent night blindness in cattle, sheep, pigs, rats and horses, Guilbert finds that either some 25–30 μgm./kgm. body weight (1 μgm. = 10^{-6} gm.) of β-carotene or 6–8 μgm./kgm. of vitamin A is needed daily.

Outspoken vitamin A deficiency is characterized by widespread atrophy of epithelial structures and often by xerophthalmia, but retardation of growth (weight) is the criterion most readily amenable to quantitative interpretation.

The diet of the majority of town dwellers shows inadequate vitamin A activity, especially during the winter months. It is also certain that most winter milk from stall-fed cattle is inferior to summer milk. Artificially dried grass is superior to hay both in respect of protein and provitamin A content, and its value as a feeding stuff has been established in many well-controlled experiments. The addition of vitamins A and D to margarine is a valuable way of alleviating vitamin deficiency, but the problem of utilizing the available resources to the best advantage and of increasing the supply to meet the known needs has not been solved. That it is necessary and possible to do so cannot be doubted, nor that the cost of effective action would be a small fraction of the cost of inaction.

This raises the point of the relative efficiency of carotene and vitamin A. The accepted unit of vitamin A activity is that exerted by 0·6 μgm. of pure β-carotene, so that the pure substance has a potency of $1{\cdot}66 \times 10^6$ I.U./gm. (by definition). Vitamin A, according to the best available data, has a potency near $3{\cdot}0$–$3{\cdot}3 \times 10^6$ I.U./gm., whereas all provitamins other than β-carotene have an activity near $0{\cdot}83 \times 10^6$ I.U./gm. These figures apply to rats receiving minimal doses.

There is urgent need for more research on the relative efficiencies of provitamins and vitamin A at the level needed to convert a marginal diet into an optimal diet.

The commonly accepted view that the equation

$$\underset{\beta\text{-carotene}}{C_{40}H_{56}} \xrightarrow{2H_2O} 2C_{20}H_{29}OH$$

corresponds with a process occurring *in vivo* would lead to 1·56 × 10⁶ I.U./gm. for pure vitamin A. This is not in accord with experience; it rests upon the assumption that fission occurs exclusively at C15—15′ double bond, and its only advantage is that it agrees with the superiority of β-carotene over other provitamins. Unsymmetrical fission is more plausible and an equation

$$\underset{\beta\text{-carotene}}{C_{40}H_{56}} \rightarrow C_{20}H_{29}OH + \text{decomposition products}$$

is in closer harmony with the observed potency of vitamin A.

Vitamin A is estimated spectroscopically by utilizing the absorption maximum at 325 mμ. There is at present no reason to justify changing the accepted conversion factor, namely:

$$E^{1\%}_{1\text{cm.}}\ 325\ \text{m}\mu,\ 1 = 1{,}600\ \text{I.U./gm.}$$

The estimation of carotene in dried grass and similar materials involves extraction of the pigments, preparation of non-saponifiable extracts and a phase separation (that is, partition between petrol ether and 90 per cent methyl alcohol). The provitamins appear in the hydrocarbon solvent and the xanthophyllic compounds are eliminated in the aqueous methyl alcohol. Chromatographic adsorption permits a finer separation of individual carotenoids, specially prepared alumina, lime, calcium carbonate, magnesia and soda ash being good absorbents for particular purposes. The carotene, freed from 'xanthophylls', is evaluated spectroscopically or colorimetrically.

Dried grass and similar products are now important sources of provitamin A for animal feeding. The following method of analysis has been thoroughly tested and found to be satisfactory by the Grass Driers' Association:

> 0·25 gm. dried grass is ground thoroughly with sharp silver sand (5 gm.) and the mixture is treated with a mixture of acetone (15 ml.) and petrol ether (45 ml.) in a continuous drip extractor for at least 1 hour. The cooled extract is transferred to a separating funnel using a little petrol for washing in, and 30 per cent methyl alcoholic potash (5 ml.) is added. Vigorous shaking for two to five minutes is followed by addition of water (200 ml.). Carotene remains in the petrol, and after washing with water (200 ml.) the 'xanthophylls' are removed by shaking the petrol ether three times with 90 per cent methyl alcohol. The petrol layer is retained and made up to known volume. A solution of potassium dichromate (0·025 per cent) is colorimetrically equivalent to a solution of β-carotene containing 0·158 mgm. per 100 ml. petrol ether.

The estimation of carotene is complicated by the presence in the petrol ether fraction of a variable amount of an *X*-substance, which may be eliminated by filtering through a short column of alumina after adding 3 per cent of acetone. A yellow impurity is adsorbed but the carotene is carried through. Dr. Kon has confirmed the observation that the percentage of this contaminant increases in dried grass on storage.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

COLUMBUS MEETING

BY DR. F. R. MOULTON, PERMANENT SECRETARY OF THE AMERICAN ASSOCIATION

IN many respects the American Association for the Advancement of Science is similar to the British Association, which served as a model for its organization and early development. It is the great democratic scientific organization of America (using the word in the geographical, not the national, sense), including in its interests all of science and its applications and relations to society. During a period of rapid increase in specialization and the organization of special scientific societies, it has served as an integrating agency. The breadth of its scope and the number of its members, now exceeding 20,000, make its voice more and more the voice of science in America.

In certain respects, however, the American Association differs from the British Association. Perhaps the least important is that it holds two meetings each year, the annual meeting during the Christmas holiday week (this year December 27—January 2, inclusive) and another meeting in the summer, usually the latter part of June. In addition, because of the large area of America, it has two geographical divisions, the Pacific Division and the Southwestern Division, each of which holds one meeting each year. A greater difference between the two associations is in the nature of their programmes. Before stating this difference, I wish to point out that many special scientific societies and organizations, at present 174 of them, are affiliated with the American Association, meet with it at their option, and have representation on its Council, its supreme governing body. As a consequence of this organization, the American Association programmes, instead of consisting of a rather small number of important addresses by distinguished men of science, include many sessions before which hundreds of papers are read. At the recent meeting in Columbus, Ohio, in about four days a total of 259 scientific sessions were held, before which 2,154 addresses and papers were presented. Naturally there was none of the delightful leisureliness of the meetings of the British Association.

Although many, probably most of the 2,154 papers presented at the Columbus meeting were of no considerable importance, yet a considerable number were distinguished. As an example, I may refer to the paper by I. I. Rabi on "Radio Frequency Spectra of Atoms and Molecules", for which the Thousand Dollar Prize of the Association was awarded. Dr. Rabi not only discovered radiations from atoms of much lower frequency than hitherto known, but also devised a method of determining their properties although they are far too feeble to be detected by any of the devices previously in use. It is not possible to pick out from the hundreds of other papers—75 in physics, 44 in chemistry, 56 in astronomy, more than 300 in the zoological sciences, more than 350 in the botanical sciences, an equal number in genetics and other general biological sciences, 67 in the medical sciences, 310 in agricultural science—a few for special comment without injustice to many others.

On the whole, the best part of the programme from the point of view of direct contributions to science was the symposia, often organized and presented by several sections and societies in co-operation. These symposia were on such subjects as "Applications of Mathematics to the Earth Sciences", "Photosynthesis", "Fifty Years of Entomological Progress", "Speciation", "Effects of Science upon Human Beings" and "Blood, Heart and Circulation". The Association has published in book form the most important of the symposia presented at its meetings during the past three years.

Perhaps the foregoing paragraphs might lead the reader to conclude that the programmes of the American Association do not include the general sessions which are so characteristic of meetings of the British Association. The American Association has such general sessions, often of distinction, but relatively to the remainder of its programme they are much less important than those of the British Association. In addition to the address of the retiring president of the Association, there are two regular evening general sessions, one under the auspices of the Society of the Sigma Xi, an honorary scientific society, and one under the auspices of the Phi Beta Kappa, an honorary scholarship society. The retiring president of the Association, Dr. Wesley C. Mitchell, chose for the subject of his address "The Public Relations of Science" [see NATURE, Feb. 10, p. 207]. The annual lecture under the auspices of the Society of the Sigma Xi was delivered by Dr. Kirtley F. Mather on "The Future of Man as an Inhabitant of the Earth". The Phi Beta Kappa address was by Dean Marjorie Hope Nicolson on "Science and Literature".

This year saw the initiation of two new general sessions, one under the auspices of the Honor Society of Phi Kappa Phi and the other under the arrangement between the British Association and the American Association for exchange lectures on alternate years. The former was delivered by Dr. Isaiah Bowman, president of the Johns Hopkins University, whose subject was "Who is Responsible for Peace ?" As British men of science will recall, Dr. Bowman was invited by the officers of the British Association to deliver at its meeting last September the first of the British and American Association Lectures.

Although the first lecture by a British man of science under the arrangement was not due until next June, the arrival of Dr. Julian S. Huxley in America just before the Columbus meeting presented an opportunity that could not be neglected. He was invited to deliver the first lecture by a British scientific worker and accepted the invitation. His subject was "Science, War and Reconstruction". In referring to this brilliant address in my report of the meeting, I wrote as follows :

"The address of Dr. Huxley illustrated the scientific ideals of impartiality, justice and altruism, not simply as ideals without immediate applications but as ideals that are urgently needed at this hour. Obviously there is now a tide in the affairs of scientists that taken at its flood may enable them to make the greatest contribution to the progress of mankind in the history of the world, but neglected may leave them in the position of having provided the bark on which civilization will drift back into the darkness from whence it came. It is gratifying that so many addresses and programs of the association and its affiliated societies gave concrete evidence of a deep feeling of responsibility of scientists to society. These responsibilities include also the more fundamental one of laying foundations for an organization of society based on the essential nature of man ; and they include the still deeper one of deriving from the laws of the inanimate and animate universes about us and within us a basis for ethics whose authority for acceptance shall be in our own hearts."

OBITUARIES

Prof. Alfred Wohl

PROF. ALFRED WOHL died in Stockholm on December 25, 1939, at the age of seventy-six years. He was born on October 3, 1863, at Graudenz and received his early training at the Universities of Heidelberg and Berlin. He obtained his doctorate in 1886 at the University of Berlin, working under the supervision of Prof. A. W. von Hoffman, and spent the next two years in the Laboratorium des Vereins für Rübenzuckerindustrie, Berlin. In 1891 he became *Privat-dozent* in Emil Fischer's laboratory in the University of Berlin, and in 1904 was appointed director of the Laboratory for Organic Chemistry and Technology at the Technische Hochschüle, Danzig, a post which he held until he retired on reaching his seventieth birthday in 1933.

During a period of almost fifty years uninterrupted research, Wohl made many important contributions to both organic and physical chemistry. His early connexion with the sugar industry probably laid the foundation for his deep interest in this branch of organic chemistry. We owe to him methods for the degradation of sugars, the preparation of the optically active glyceraldehyde and much of our early knowledge of fermentation enzymes. He also devised methods of making artificial honey which are still in use to-day, and during the War of 1914–18 produced an economical process for growing yeast.

In other branches of organic chemistry, Wohl carried out the synthesis and investigation of many important compounds such as phenylhydroxylamine, the semi-aldehyde of malonic acid, malic and tartaric dialdehydes, lactic acid aldehyde, the acetal of methyl glyoxal, and the preparation of glyoxal by the interesting method of the ozonization of acetylene. He also showed that nitrobenzene reacts with potash to give nitrophenol.

One of Wohl's outstanding achievements was the demonstration of the wide applicability of vanadium pentoxide as an oxidation catalyst; by its use he carried out the oxidation of naphthalene to phthalic anhydride and of anthracene to anthraquinone, and thus opened a new path to the cheap production of intermediates for the dyestuffs industry.

Wohl always showed a fervent interest in the theoretical aspects of organic chemistry, and developed a theory of chemical reactivity based on Michael's theory of primary association of reaction spots and on the polarity of linkages. Much of his work was devoted to the substantiation of these ideas and in this respect he made special studies of the reactivity of bromacetamide, hydrazonium compounds, and of the Friedel-Crafts synthesis. His interest in theory extended to physical chemistry and his most important contribution in this field was the formulation of an equation of state for gases, based upon a simple modification of van der Waals' equation. He also published a series of papers in the *Berichte* on methods of analysis of gases. In developing these methods, he devised a new type of glass tap and also a means of producing vacua suitable for low-pressure distillations by the use of charcoal cooled by liquid air and an ordinary filter-pump.

Wohl was a man of outstanding personality and an enthusiastic, ardent, and inspiring teacher. He spared no effort to help his students, and during term it was his daily practice to gather them together in small groups in the laboratory and discuss with them their research problems.

Many honours were conferred on Wohl. He held the office of president in the Deutsche Chemische Gesellschaft in 1933 and was given the honorary degree of Dr.Ing. of the Technische Hochschüle, Hanover, in 1928, and Dr.Agr. of the Landwirtschaftliche Hochschüle, Berlin, in 1931.

Although he retired in 1933, he carried on experimental work until 1938, and in his last years developed a process for the manufacture of pulp from fibrous vegetable materials.

Mr. R. A. Smith

WE regret to record the death, at the age of sixty-six years, of Mr. Reginald A. Smith, formerly keeper of the Department of British and Medieval Antiquities of the British Museum, which took place at Colchester on January 13.

Reginald Allender Smith was born in 1873 and educated at Christ's Hospital and University College, Oxford. In 1898 he was appointed to the staff of the British Museum in the Department of Ethnography and British and Medieval Antiquities, as it then was, of which Charles Hercules Read was at that time keeper. Smith was assigned to the archæological collections, of which he became keeper in 1927, after the ethnographical collections had become a distinct department. He retired in 1938.

Smith was fortunate both in his chief and in the nature of his duties—the care and arrangement of the prehistoric and early historic collections of antiquities of the Museum. By his association with Read he was trained in that appreciation of the significance of form and technique in which his chief was pre-eminent, while his care for, and arrangement of, the collections committed to his charge developed to the full his capabilities of scientific precision in observation and interpretation of detail which enabled him during a period of nearly forty years to make to the advancement of archæological studies a contribution which was no less valuable than it was individual, and, indeed, unique.

A variety of circumstances combined to afford Smith the opportunity to attain the position which he afterwards held in the archæological world. Of these, one of the most influential was the part assigned to him in carrying out the policy initiated early in his career at the Museum of issuing guides to the archæological collections, of which the first, on the Stone Age, appeared in 1902. Smith was mainly or solely responsible for the valuable guides, both in the original and in the revised editions, to the Stone, Bronze, and Iron Ages collections as well as to those of the Romano-British and Anglo-Saxon periods.

The preparation of these guides demanded an intimate and detailed knowledge and understanding of the characteristics of each individual specimen in the collections in relation to general typology as well as to the development of theoretical reconstruction in prehistoric and early historic studies. An even broader view was demanded in Smith's contribution of archæological chapters to early volumes of the "Victoria History of the Counties of England", which had commenced publication also early in Smith's career.

This thorough grounding in knowledge of the detailed evidence bearing upon British archæology proved of enormous service to scientific studies when Smith in 1908 joined the Council of the Society of Antiquaries of London, and afterwards became its honorary secretary and then its director, an office which he held for many years. Through the ramifications of the Society's many activities he was in close touch with archæological research in the field throughout Britain as well as on the Continent. Not only did he himself make many valuable contributions to archæological literature in its technical periodicals—his most considerable publication was an exhaustive illustrated catalogue of the Sturge collection of stone implements—but also he came to be widely recognized as, in a sense, a court of final appeal on the value and significance of any new discovery, or any fresh evidence bearing on previously ascertained facts in the prehistoric field of Britain. In the records of archæological discovery of the last twenty years, no name, with the possible exception of that of the Abbé Breuil, is more frequently quoted as responsible for an authoritative and final opinion than that of Reginald Smith.

Mr. G. L. Bates

Mr. G. L. Bates, who died on January 31, was born in the State of Illinois in 1863. He was the eldest son of a large family, and inherited his love of natural history from his mother. He was educated at Galesburg and Chicago, and it was his father's wish that he should enter the Church. However, he had a great desire to travel and study Nature, and he persuaded his father to send him to West Africa in 1895. His first years were spent in Gabon and the French Congo, and later he settled in the former German colony of Cameroon.

In 1896 Bates began to send collections to the British Museum, and up to 1928 there was a steady stream of specimens in all groups. Though primarily an ornithologist, Bates did not confine his collecting to birds, and he had the reputation as a very successful collector of reptiles, discovering some sixty-two new species, including *Rana goliath* and *Trichobatrachus robustus*, the curious hairy frog. In mammals, too, he made many discoveries, and his specimens of plants and fishes are models of careful collecting. From 1923 onwards he made many expeditions to different parts of West Africa, including a trip to the Southern Sahara, where he made some interesting observations on the affinities of the Saharan avifauna. Later he undertook the study of Arabian birds, and in 1934 paid a visit to Mr. H. St. J. Philby at Jedda.

Apart from his expeditions, Bates will always be remembered for his papers on the reversed under-wing coverts of birds, and his study of the genus Smithornis. In this last he proved by anatomical evidence that the genus had nothing to do with the normal Passeres. This was confirmed later by P. R. Lowe, who demonstrated that the true position was in the Asiatic Eurylæmidæ. Perhaps Bates's most important contribution to ornithology was on the "Geographical Variation within the Limits of West Africa", in which he showed that these variations, whether in colour or size, fall within certain rules. In 1930 he published a useful little "Handbook of the Birds of West Africa".

Bates's shy and retiring nature was increased by long residence alone, but nevertheless, no one was more ready to help others, and he will be missed by many. In the late autumn he underwent a serious operation from which he never fully recovered.

N. B. Kinnear.

Prof. Fritz de Quervain

Prof. Fritz de Quervain, an eminent Swiss surgeon, who died last month at the age of seventy-one years, was born at Sion, the capital of the Valais Canton, on May 4, 1868. He received his medical education in Bern, where he was assistant to Kronecker the physiologist from 1889 until 1891 and to Langhans the pathologist from 1891 until 1892, when he qualified. For the next two years he was assistant in Kocher's surgical clinic, and then entered on a surgical practice at Chaux-de-Fonds, where he became director of the surgical clinic in 1897. In 1902 he returned to Bern, where he remained until 1909, when he was appointed professor of surgery in the Basle faculty of medicine, and finally in 1918 occupied the corresponding chair at Bern.

We regret to announce the following deaths:

Lieut.-Colonel J. A. Amyot, C.M.G., lately Canadian deputy minister of pensions and national health, formerly professor of hygiene in the University of Toronto, aged seventy-two years.

Colonel R. E. B. Crompton, C.B., F.R.S., a pioneer in electrical engineering and mechanical road traction, on February 15, aged ninety-four years.

Mr. H. G. Newth, lecturer in zoology in the University of Birmingham, on February 17.

Prof. C. Tangl, director of the Institute of Experimental Physics, University of Budapest, on December 10, aged seventy-one years.

NEWS AND VIEWS

Waynflete Professor of Physiology, Oxford

ANNOUNCEMENT has been made of the appointment of Dr. E. G. T. Liddell, of Trinity College, Oxford, to the Waynflete chair of physiology in the University of Oxford, which has been vacant since last autumn owing to the death of Prof. J. Mellanby. Dr. Liddell graduated in medicine from Oxford and St. Thomas's Hospital, and returned to the University as assistant in physiology in 1921. He collaborated in much of the later work of Sir Charles Sherrington, including the studies on the stretch reflex, the publication of the "Reflex Activity of the Spinal Cord", and the revised second edition of "Practical Exercises in Mammalian Physiology". He was thus intimately associated with the Sherrington School. His particular interest has naturally been the physiology of the nervous system, and his more independent published papers have been concerned with studies on the knee-jerk, physiology of the cerebellum and spinal cord. He has also published work on the experimental production of high blood pressure in animals. Latterly he has elaborated a technique for study of the postural reactions in the limbs of the intact animal over a long period of time, thus exploring the effects of lesions of the spinal cord and corpus striatum by operative means. He has made himself an authority on this particular branch of the subject, hitherto neglected in Great Britain.

Prof. Liddell was elected fellow of the Royal Society last year. As fellow of Trinity College, Oxford, since 1921, he has gained a wide reputation as tutor and will be greatly missed in this sphere of university life. His long experience as examiner and tutor, his wide interests and thoughtful outlook, all combine to make him unusually well suited to the chair, and we wish him every success.

Guthrie Lecturer of the Physical Society

THE twenty-fourth Guthrie Lecture of the Physical Society will be delivered at 5.30 on February 26 at the Royal Institution by Prof. P. M. S. Blackett, professor of physics in the University of Manchester. The subject of the lecture is "Cosmic Rays: Recent Developments". Prof. Blackett served with the Royal Navy in 1914–19, having previously been at the Royal Naval Colleges at Osborne and Dartmouth. After the War he exchanged a naval for a scientific career and went up to Magdalene College, Cambridge. In the Cavendish Laboratory he began work with the Wilson cloud chamber, a technique of research to which he has remained faithful. His work during 1923–1933 was concerned with the alpha particle. He showed that alpha particles make nuclear collisions in which energy and momentum are very accurately conserved, but he also investigated collisions resulting in nuclear disintegration, and showed, for the first time, that in a Rutherford disintegration of the nitrogen nucleus the alpha particle is absorbed and a proton liberated.

In 1932 Blackett developed the counter-controlled cloud-chamber device—a method of using the cloud chamber in which the expansion is initiated by the passage of the particle to be photographed. This has proved to be a most valuable instrument. This work led immediately to the detailed study of cosmic ray particles; and Blackett and Occhialini found, almost at the same time as Anderson, that positively charged particles of electronic mass occur in the cosmic rays. With Chadwick and Occhialini, Blackett showed the formation of positrons by the passage of hard gamma rays through lead. Since that time Blackett has concentrated almost entirely on the subject of cosmic rays. He has initiated investigations at Cambridge, at London (Birkbeck College) and at Manchester; indeed most of the experimental work on cosmic rays in Great Britain has been inspired by him more or less directly. His own work has been chiefly concerned with the energy spectrum of the particles, which he has investigated by means of a very refined cloud chamber in a strong magnetic field.

Prof. D. R. R. Burt

MR. DAVID R. R. BURT, who has just been made professor of zoology in University College, Colombo, has had charge of his department since 1924, and has raised it from small beginnings to a school of more than a hundred students. Prof. Burt is a graduate of St. Andrews, and was at one time an assistant to Sir D'Arcy Thompson; he also worked under Hans Przibram in Vienna. He has studied, among other things, the very numerous cestode parasites of the Ceylon fauna. Some years ago he devised, and described in NATURE, a method of anatomical injection with rubber-latex which has great advantages and has come into everyday use, especially in America.

Centenary of Sir Hiram Maxim

AMONG the great mechanical inventors of last century, none was known to a wider public than Sir Hiram Maxim, who was born on February 25, a century ago. When he came to Europe in 1881 to attend the Paris Exhibition, he was the engineer of the first electric light company in the United States, but was known to few in Great Britain. He had, however, already taken out a goodly number of patents, had invented a gas-making machine for lighting buildings and had done much original work on the incandescent electric lamp, dynamos, regulators, boiler plant and suchlike. When on the Continent, his attention was attracted to the subject of machine-guns. His countrymen Gatling, Gardner, and Hotchkiss had all invented machine-guns, and so had the Swedish engineer Nordenfelt. None of their guns, however, had proved entirely satisfactory.

In Paris Maxim drew the design of his gun, and his original gun was made in a workshop at 57A Hatton

NATURE

SUPPLEMENT

Vol. 145 SATURDAY, FEBRUARY 24, 1940 No. 3669

SHORT REVIEWS

BIOLOGY

(1) Bacteriology
For Medical Students and Practitioners. By Prof. A. D. Gardner. (Oxford Medical Publications.) Second edition. Pp. viii+274. (London: Oxford University Press, 1938.) 6*s*. net.

(2) The Microscope Made Easy
By A. Laurence Wells. Pp. 182. (London and New York: Frederick Warne and Co., Ltd., 1938.) 3*s*. 6*d*. net.

(1) PROF. GARDNER has managed to include in this small book a surprising amount of information on bacteriology, which is adequate for the medical practitioner who desires to keep abreast of advances in the subject, as well as being detailed enough for the medical student, with some supplementary reading. The matter is well presented and readable, singularly free from errors, and well up to date. Apart from the descriptions of the pathogenic micro-organisms and their effects, such subjects as immunity and antibody-antigen reactions, agglutination and anaphylaxis, and bacterial variation, are particularly well done, and the author has managed to include short sections on disinfection and the bacteriology of water and milk. The additional chapter on viruses in this second edition gives an excellent general account of the subject, together with sections on microscopical visibility and the bacteriophage. This is a book that can be cordially recommended.

(2) Mr. Wells's book, as its title implies, is a simple guide to elementary microscopy. The descriptions are easy to follow, and accounts are given of the microscope, and how to examine and mount a number of objects—crystals, pond life, diatoms, etc. The book contains several plates which satisfactorily illustrate and name a number of the objects mentioned in the text. The beginner without previous knowledge of microscopy will find it a useful first book on the subject. R. T. H.

The Fauna of British India, including Ceylon and Burma

Edited by Lt.-Col. R. B. S. Sewell. (Published under the Patronage of the Secretary of State for India.) Butterflies. Vol. 1. By G. Talbot. Pp. xxix+600+3 plates. (London: Taylor and Francis, Ltd., 1939.) 35*s*.

SINCE the publication of Bingham's volumes in the Fauna of India series in 1905 and 1907, knowledge of Indian butterflies has progressed very considerably. The issue of new volumes on these insects is, therefore, justified. In the present book there is a general and rather elementary introduction to certain aspects of the subject as a whole. External characters, variation, mimicry and distribution are dilated upon in this chapter: the rest of the volume is devoted to accounts of the species belonging to the families Papilionidæ and Pieridæ and, whenever possible, descriptions of the early stages are included.

The present work is uniform with the other volumes in the series and maintains the standard already established by its predecessors. It is a book which all who wish to know about Indian butterflies will need to consult. Some time will evidently elapse before the work is brought to completion by subsequent volumes, since only about one seventh of the recognized species are dealt with in the present contribution.

The Structure of Economic Plants

By Prof. Herman E. Hayward. Pp. x+674. (New York: The Macmillan Company, 1938.) 22*s*. net.

THIS volume is an outgrowth of the author's courses in plant anatomy at the University of Chicago. It is divided into two parts, the first dealing with general plant anatomy, and the second with the structure of a selection of plants of economic value. These are chosen partly for their economic importance, partly as typical representatives of the various families, and partly for their anatomical complexity. Fruit crops are omitted, as the author plans a second volume devoted especially to them.

Part 1, consisting of 109 pages, is an excellent condensed introduction to vegetable anatomy. In Part 2, the structure of the selected crops is treated in detail and full references to literature are given. It is, in effect, a series of monographs, and should prove very valuable to any research worker who requires an account of the basic anatomical structure of the plant he is dealing with. A special feature is the number of diagrams showing the course of vascular bundles in stems and other structures. Throughout the book the copious illustrations are, with one or two exceptions, clear and well drawn.

In matters not purely anatomical, the author's high standard is not always maintained. For example, in the discussion of the hybrid origin of 'Grimm' and other variegated alfalfas, the important genetical work of Urban (1877) and others, which puts this origin beyond doubt, is not mentioned. In the glossary, phylogeny is defined as "the developmental history of a race rather than an individual"; it would surely be preferable to substitute a broader term, such as 'group', for 'race', which has a too restricted connotation.

L'Acide ascorbique dans la cellule et les tissus

Par Prof. A. Giroud. (Protoplasma-Monographien, Band 16.) Pp. vi+187. (Berlin: Gebrüder Borntraeger, 1938.) 12 gold marks.

IN this monograph—the sixteenth of the well-known "Protoplasma" series—Prof. A. Giroud develops, from an account of his own and other histochemical studies on the distribution of ascorbic acid in plant and animal cells, an interesting general discussion of the biological function of the vitamin. Although his treatment is sometimes rather speculative and often superficial, it provides a highly stimulating review of the large literature that has grown up since Szent-Györgi announced the discovery of 'hexuronic acid' ten years ago. It well repays reading. J. C. D.

CHEMISTRY

A History of Chemistry

By Dr. F. J. Moore. Revision prepared by Prof. William T. Hall. (International Chemical Series.) Third edition. Pp. xxi+447. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 20*s*.

IN this revised edition of a well-known and valued work, the account of the earlier period has been greatly extended and new material has been added in most parts of the text. A valuable feature of the book is the attention given to American chemists; it is not generally known, for example, that Crafts was an American, although much of his work was done in France. The history is brought down to recent times, although some of the sections dealing with atomic structure are now in need of revision, and the statement on p. 406 as to the possible future use of the electron theory in organic chemistry needs rewording, in view of the extensive applications which have been made in this field. The text is very accurate and very few slips have been noted; among these is the statement on p. 337 that Mitscherlich was Russian, and the name Rausch on p. 429 for Ruark. The book is most attractively written and displays a truly philosophical outlook throughout; the new edition may be cordially recommended both to students and also the general reader. The large number of interesting illustrations should be specially mentioned.

Hand- und Jahrbuch der chemischen Physik

Herausgegeben von A. Eucken und K. L. Wolf. Band 10, Abschnitt 3: Starkeffekt, von B. Mrowka; Elektrischer Kerr-Effekt (Elektrische Doppelbrechung), von H. A. Stuart. Pp. 110+vi. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1939.) 12 gold marks.

THE first twenty-six pages are devoted to the Stark effect. This brief article will prove useful alike to physicists and physical chemists. It is written in a clear, straightforward style. After dealing with the Stark effect of hydrogen atoms and helium ions, consideration is given to the Stark effect of helium atoms, of atoms with more than two circum-nuclear electrons, and of molecules. The article concludes with a treatment of the relationship between the Stark effect and other phenomena.

All who are interested or engaged in problems of molecular structure will welcome Dr. Stuart's capable summary of the electro-optical effect first observed by Kerr in 1875 and named after him. A discussion of the theoretical aspects, occupying twelve pages, is followed by an account of the methods used in the investigation of the effect. Various factors which influence the effect are discussed and the magnitude of the influence of each is indicated. The last thirty pages illustrate the application of Kerr effect data to problems of molecular structure. Tables of selected reliable data and an extensive bibliography are given.

Both articles are treated in a clear, competent manner and can be recommended to all interested in these topics.

Inorganic Chemistry

By Fritz Ephraim. Third English edition. By Dr. P. C. L. Thorne and Dr. A. M. Ward. Pp. xii+912. (London and Edinburgh: Gurney and Jackson, 1939.) 28*s*. net.

IN preparing the new edition of this well-known book, the editors have made a number of useful additions covering recent work and have revised several parts of the text. There are still some parts of the old text which should be removed, as they are in contradiction with the new material. The point of view is more modern than was the case in previous editions, particularly in the sections dealing with co-ordination compounds, and the book is certain to maintain its well-deserved popularity with advanced students. It provides a very good survey of modern inorganic chemistry in a reasonable compass, and the references to the literature will enable both teachers and students to amplify the information on any particular subject. The printing and lay-out are very good and the book is pleasing in appearance; the price is very reasonable.

GEOGRAPHY AND TRAVEL

Transport in Many Lands

By W. Robert Foran. Pp. 260. (London and New York: Frederick Warne and Co. Ltd., 1939.) 7*s*. 6*d*. net.

MR. FORAN'S "Transport in Many Lands" is not, as its title may seem to suggest, a systematic account of the various methods of transport practised by different peoples, but to the general reader it will probably prove more entertaining. It is a record of personal experience and observation, more especially in the indulgence of a personal preference for animal transport, in the course of some forty years of travel in many of the remoter quarters of the globe. The elephant holds pride of place, both as a worker in the teak forests of the East, and as an impressive member of the pageantry of eastern princes. Some of the instances of its intelligence when logging timber are indeed, as the author describes them, almost 'uncanny'. Next to the elephant comes the camel, which as Mr. Foran points out, when discussing ancient trade routes, is one of the most ancient forms of animal transport on an economic scale employed by man. One of the most surprising uses, to which the author has put it, is as a mount for polo in Egypt. Apparently the experience was enjoyable. Following on the llama in South America and yak in Tibet, Mr. Foran deals with pack animals, the horse, mule and donkey, and then reindeer, oxen, and dogs, concluding with a chapter devoted to some of the strange vehicles and methods of transport he has seen, in which the power of man himself is harnessed. It is perhaps scarcely necessary to point out in reference to Mr. Foran's account of the reindeer that the Samoyedes and Ostiak of Siberia are not Eskimo.

In his forty years of observation Mr. Foran has witnessed a vast extension of European methods of transport among backward peoples in the use of the car and the bicycle. Nevertheless he shows how, under the influence of environment and tradition, old-fashioned methods still in many regions maintain their vitality, and usually for good reason.

L'Asie centrale soviétique et le Kazakhstan

Par Charles Steber. Pp. 302. (Paris: Éditions Sociales Internationales, 1939.) 35 francs.

THE part of Central Asia formerly known vaguely as Russian Turkestan and now comprising several autonomous republics of the Soviet Union is little known and is treated mainly in books which lack recent information. For the main part, it is an area of vast and somewhat arid plains extending southward from Siberia and eastward from the European plain, but it comprises also the mountainous little explored area in which lie much of the Pamirs and allied ranges. Formerly it was a land of sparse population and nomadic tribes, but all that is changing. Soviet influence has begun to develop its resources on a large scale. Irrigation, where possible, has led to agriculture, and the cotton output, not to say its manufacture, is already considerable. Public works, roads, railways and schools have been built, and even in the remoter mountain areas Russian influence is spreading. The author of this small but informative volume gives a clear record of the land and its progress, although his physical introduction is somewhat brief. There are simple but adequate maps and many references to authorities.

GEOLOGY

Elements of Geology

With Reference to North America. By Prof. William J. Miller. Second edition. Pp. x+524. (London: Chapman and Hall, Ltd., 1939.) 21*s*. net.

ALTHOUGH prepared primarily for American students, Prof. Miller's text-book is written in such a simple and interesting style and is so well illustrated that it should have a wide appeal. Indeed, the author arouses interest in the science at the outset, for he takes the novel course of describing, in his opening chapter, the evidence for upward and downward movements of the earth's crust and the phenomena of earthquakes—both subjects not too remote from everyday life. Thence he leads the reader to the study of minerals and rocks, weathering, rock-structure, and the work of rivers, glaciers, wind, the sea, underground water, and volcanoes. The development of scenery is also simply described. Having regard to the vast accumulation of data relating to these subjects, every author of a text-book must decide what to omit: and here Prof. Miller's selection seems to have been judicious.

The second half of the volume is concerned with historical geology and, except for the penultimate chapter on Cenozoic life, has reference only to North America. Dull stratigraphical details are avoided so far as possible and full use is made of palæogeographical maps. The section on early man in the chapter on Cenozoic life has necessarily, however, been largely compiled from the records found in the Old World, and here the author is rather less happy in his summary than elsewhere in the book. A study of articles recently published in NATURE would afford him material help, and the author might find it worth while to seek the assistance of some geological and archæological friends in Europe in wending his way through the tangle of conflicting accounts of the history of man. The volume is of such quality as to justify the effort.

Ground Water

By Prof. C. F. Tolman. Pp. xvii+593. (New York and London: McGraw-Hill Book Co., Inc., 1937.) 36*s*.

THIS book makes a notable addition to the literature of ground-water hydrology. The author assumes the reader to possess an elementary knowledge of geology and of hydraulic engineering, and the introductory historical chapter mentions the importance of co-operation between geologist and engineer in the study of sub-surface waters. Chapter ii states the general principles controlling the occurrence and behaviour of ground-water, with terms defined, and is intended to provide a summary suitable for the lawyer preparing litigation on the subject; numerous page-references are given in the index under the general heading 'Litigation'. Chapters follow with a detailed discussion of rainfall, porosity, soils, flow of ground-water, and the water-table, the last containing a 24-page appendix on prospecting for water by geophysical methods, contributed by C. A. Heiland.

Selected references to literature (mainly American) are given at the end of each chapter. Water in fractures, artesian supplies, wells, oil-field fluids, and springs form the subjects of further sections. The last two chapters deal respectively with quantitative methods of measurement (with extracts from publications by O. E. Meinzer) and the distribution of underground water in the United States and the Hawaiian Islands. The book is illustrated by 189 good text-figures; most of the water-table contour maps in Chapter ix lack a statement of scale, which would have been helpful in estimating water-table gradients. There is a useful glossary of more than a hundred terms and a generous index.

MATHEMATICS

An Introduction to Modern Statistical Methods

By Paul R. Rider. Pp. ix+220. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 13*s*. 6*d*. net.

THIS text-book on statistical methods is intended for the student who is interested in applications, but who at the same time, while not aiming at a complete knowledge of the underlying mathematical theory, would like to get a grasp of the main principles and formulæ. It is thus introductory both to theory and application, and although the discussion sometimes seems more fragmentary than one would wish, the author has welded the two aspects together into a fairly unified course.

The statistical concepts of frequency distributions, averages and moments, regression, and correlation, are first explained, before sampling and significance problems are dealt with. After a chapter on the binomial and normal distributions, the author then discusses the use of "Student's" and the χ^2 distributions, before concluding with the general principles of analysis of variance and experimental design. Statistical tables required for significance tests are included at the end of the book, and appended to each chapter is a useful collection of examples. It should be noted that in his discussion of the χ^2 test of goodness of fit (p. 108), the author omits to warn the reader of the necessity for *efficient* estimation of unknown parameters; in fact, the whole problem of estimation, even for an introductory text-book of this kind, seems scarcely adequately discussed. M. S. B.

An Introduction to the Theory of Functions of a Real Variable

By S. Verblunsky. Pp. xi+170. (Oxford: Clarendon Press; London: Oxford University Press, 1939.) 12*s*. 6*d*. net.

TO the ordinary mathematical student, geometrical illustrations in a text-book on analysis are a relief and an inspiration; to the purists the use of figures is a weakness. They demand that the theory shall be based on arithmetical considerations alone. Mr. Verblunsky's treatise completely satisfies this demand. For the student of analysis who is already acquainted with the subject, a careful reading of this book should be a useful discipline in careful and logical statement. For the usual type of honours student a course of this kind would, we fear, be disastrous.

The volume starts at the beginning of the subject—with the positive integers—and leads on by carefully graduated steps to the study of functions, sequences, derivatives, limits and integrals, closing with a chapter on infinite series. There are numerous illustrative examples, most of them fully worked out; but no sets of examples for practice are provided.

Mr. Verblunsky's exposition is, in the main, clear, concise and accurate. We deprecate, however, his method of introducing irrational numbers. This he bases on the following "Postulate of the Continuum". If, for every n,

$$a_n \leqq a_{n+1} \leqq a_n + (\tfrac{1}{2})^n,$$

then there is just one number ξ such that, for every n,

$$a_n \leqq \xi \leqq a_n + (\tfrac{1}{2})^{n-1}.$$

This postulate is flung at the reader with practically no explanation or discussion. The effect on the beginner is bound to be bewildering. If the book is to be used as a text-book it will be necessary for the teacher to lead up to the postulate by some sort of explanatory introduction.

MEDICAL SCIENCE

Medical Entomology

With Special Reference to the Health and Well-being of Man and Animals. By Prof. William B. Herms. Third edition, based on the book known as "Medical and Veterinary Entomology". Pp. xx+582. (New York: The Macmillan Company, 1939.) 24*s*. net.

WITH the present volume, and those by Matheson and by Riley and Johannsen, the student of medical entomology is very well catered for in North America. Prof. Herms has, in this book, brought out a complete revision of his "Medical and Veterinary Entomology", the second edition of which appeared in 1923. Since that time an enormous amount of information has accumulated. Its sifting and compression, necessitated in a book of this kind, is no light task, and Prof. Herms has accomplished the feat with notable success.

All the more important diseases and other affections of man, and of domestic animals, in which insects and arachnids are implicated as carriers or as causative agents, come in for discussion. In addition to six chapters of a more or less general character, some fourteen chapters are devoted to insects in relation to disease, two chapters to arachnids in the same connexion, together with a chapter on venomous and urticarial arthropods and a final one dealing with the utilization of arthropods in medical practice.

Written in a clear, terse style, a great deal of valuable information is compressed in rather fewer than 600 pages. Prof. Herms's book can be confidently recommended as an up-to-date guide to its subject.

The Genuine Works of Hippocrates

Translated from the Greek by Dr. Francis Adams. Pp. ix+384+8 plates. (London: Baillière, Tindall and Cox, 1939.) 13*s*. 6*d*.

THIS volume appears to be a reproduction in book form of Francis Adams' translation for the Sydenham Society in 1849, which Dr. Emerson Crosby Kelly, the editor, had already published in *Medical Classics* for September, October and November, 1838. It contains the following works of Hippocrates which Adams regarded as genuine: The Oath, On Ancient Medicine, On Airs, Waters and Places, On the Prognostics, On Regimen in Acute Diseases, First and Third Books of the Epidemics, On Injuries of the Head, On the Surgery, On Fractures, On the Articulations, Mochlicus, Aphorisms, the Law, On Ulcers, On Fistulæ, On Hæmorrhoids, and On the Sacred Disease. The present edition has the advantage over the Sydenham Society's publication in consisting of only one volume instead of two, but this has been effected by the omission of (1) Adams's Preliminary Discourse, which deals with the life of Hippocrates, his disquisition on the authorship of the different treatises attributed to Hippocrates, and the physical philosophy of the ancients, (2) Adams's introductions to the various treatises contained in the volume, and (3) almost all the footnotes as well as a considerable number of the entries of the index. The present edition, therefore, will be more acceptable to the general reader than to the medical historian, who will miss the learned commentaries of one of the most famous authorities in classical Greek medicine.

MISCELLANY

The Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland

With a Record of Publications issued during Session 1938–1939. Compiled from Official sources. Fifty-sixth annual issue. Pp. vii+175. (London: Charles Griffin and Co., Ltd., 1939.) 10*s*.

IN spite of the dislocation of the work of scientific and learned societies by the War, the publishers state in their preface to this useful reference book that they hope to continue to produce it. Indeed, in view of present difficulties, it is a matter for congratulation that the book has appeared so promptly, and that no increase has been made in the price. The volume is slightly larger than last year's issue, and contains the usual information relating to the addresses, publications and other activities of scientific and learned institutions, including such official bodies as the Department of Scientific and Industrial Research. In many cases the bodies referred to will no doubt have war-time addresses, but it may be assumed that correspondence addressed to their permanent homes will eventually reach them.

The Theory and Practice of General Science

By H. S. Shelton. Pp. 123. (London: Thomas Murby and Co., 1939.) 3*s*. 6*d*. net.

MR. SHELTON'S book is written chiefly in support of a detailed syllabus of general science, which he has arranged in the form of topics, and it may be said at once that the syllabus is a good one. He himself seems to be in no doubt about it, for he writes: "To those who desire to found a course of general science, it can be said quite simply and clearly: Here it is for the first time in a simple, intelligible and coherent form". Mr. Shelton is severely critical of all other syllabuses of general science, especially those which have recently been compiled by the Science Masters' Association. He seems, however, to have misunderstood their aim, which was not to mark the end of thought, but to display a content of teaching material which masters could employ in arranging their own schemes of work. For this purpose, the form in which the S.M.A. printed its material is more useful than Mr. Shelton's, since it can be adapted more easily to special circumstances.

Outlines of the History of Architecture

Part 4: Modern Architecture, with particular reference to the United States. By Prof. Rexford Newcomb. Pp. xv+318. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 20*s*. net.

IN the history of architecture class at the University of Illinois, Prof. Rexford Newcomb found it necessary to devise means whereby both lecturer and students could make full use of their opportunities. In these courses, which are largely presented by the illustrated lecture method, the students were compelled to write almost continuously in a darkened room, and much of the consequent distraction from the subject itself was obviated by supplying them with mimeographed sheets giving bibliographies, references, class assignments and directions—in fact, all the routine notes the writing down of which has no exercise value. From these sheets this very unusual book has been developed, and the author has done well to preserve and publish the valuable digest of the facts and examples on which his lectures were based. The fourth volume of the series is concerned with modern architecture—say from the beginning of the eighteenth century—and while American architecture is more freely referred to, historical, bibliographic and other data are collated from France, Great Britain, Germany, the Low Countries and Scandinavia.

PHYSICS

Electricity and Magnetism

An Introduction to the Mathematical Theory. By Prof. John B. Whitehead. (Electrical Engineering Texts.) Pp. xi+221. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 19*s.* 9*d.*

THE professor of electrical engineering of the Johns Hopkins University has written a compact introduction to electricity and magnetism in which stress is laid on the physical and mathematical theories. The historical order is adopted, and the first six chapters are concerned with electrostatics. A single chapter on magnetism is followed by chapters on electrodynamics and electromagnetism, and the electrical units receive special attention. The chapters on alternating currents are of value and deserve mention, as they include an elementary account of modern methods of computation. Finally, a brief description is given of the theory of conduction in gases. To condense so much into little more than two hundred pages is a noteworthy feat, and the author is to be congratulated on his presentation of the subject.

Matter, Motion and Electricity

A Modern Approach to General Physics. By Henry De Wolf Smyth and Prof. Charles Wilbur Ufford. Pp. xiii+648. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 25*s.*

UNIVERSITY teachers of physics who are not fettered by examination requirements and can plan their own courses will find this stimulating volume suggestive and helpful. Designed for a first-year course at Princeton, the book does not profess to cover the whole range of physics; but it deals with subjects related to the great theme of atomic and molecular constitution. It will therefore appeal to the chemist as well as to the eager student who wishes to plunge at once into the latest results of modern research on the properties of matter and of electricity. The advantages of the practical electrical units are so great that the authors have been led to adopt from the outset the M.K.S. (metre-kilogram-second) system of units.

Cosmic Rays

Three Lectures, being the revision of the 1936 Page-Barbour Lectures of the University of Virginia and the 1937 John Joly Lectures of Trinity College, Dublin. By R. A. Millikan. Pp. viii+134+22 plates. (Cambridge: At the University Press, 1939.) 8*s.* 6*d.* net.

THE first and perhaps the most important lecture is of a general character, in which, together with an account of the historical development of the subject, Millikan provides an answer to the often recurring question: What good are cosmic rays? He discusses the supreme social importance of abstract scientific knowledge, first in its applications to everyday life, although these may be delayed for generations, secondly in providing the example of a network of established fact to such subjects as economics, politics, etc.

The second lecture is an account of the various particles—positive and negative electrons, protons, photons and mesotrons, and of their discovery. It is noteworthy that throughout the book there is no mention of the instability of the mesotron, nor except in a footnote of its theoretical importance.

The last and longest lecture is a study of the latitude effects, both at sea-level and high in the atmosphere. It is valuable in giving in one place a full account of all the work of Millikan and his collaborators in this field, but is somewhat confusing reading, especially to those unfamiliar with the subject, as the historical development is given in detail. All the misconceptions, difficulties and mistakes of the past are treated with equal emphasis as the extent of our present knowledge.

PSYCHOLOGY

General Psychology

By J. P. Guilford. Pp. xii+630. (London: Chapman and Hall, Ltd., 1939.) 18*s.* net.

THIS book is divided into six parts. The first contains a discussion, on traditional lines, of the scope of the subject and a brief outline of the nervous system. A thorough and highly satisfactory section follows dealing with sensory activities and the processes of attention. The chapters on vision and hearing are noteworthy. The remainder of the book deals with the following topics: motivation of behaviour; acquiring new adjustments; symbolic activity, that is, images, concepts and language; and individual differences in ability and personality. The weakest chapters are those on human personality, which do not reach the standard set by the rest of the work.

The book is designed as an introductory experimental text, and each chapter concludes with a series of questions planned to test the student's grasp of the chapter. There are numerous diagrams and graphs, and the material is presented with clarity and simplicity. The student of psychology in Great Britain will welcome this interesting and up-to-date exposition of his subject.

The Mind of the Bees

By Julien Françon. Translated by H. Eltringham. Pp. xi+146. (London: Methuen and Co., Ltd., 1939.) 6*s.* net.

THIS little book is a reliable translation of "L'Esprit des Abeilles," the author of which is an original investigator and a good observer. His work has been carried out on foraging bees and not on bees within the hive. He appears, however, to under-estimate the importance played of odours in bee-behaviour, and claims that the first-comer communicates the location of a food source to the other foragers, who are thus enabled to find it. These and many other observations are carried out in a scientific manner, but the deductions made therefrom are more open to criticism. In spite of whatever defects the book may have, it is suggestive and well worth reading.

Garden, London. In it Maxim used the force of the explosion to work the breech mechanism, and for the first time produced a fully automatic gun. The Maxim Gun Company was formed in 1884 and soon it was supplying guns to many armies. In the 'nineties Maxim began his experiments with steam-driven 'captive' flying machines, on which he spent many thousands of pounds. He knew he was trying to achieve something thought impossible, and if he had little success he at least brought the subject of aeronautics into the limelight. Scores of distinguished men, including King Edward VII, then Prince of Wales, visited Baldwyns Park in Kent and rode on Maxim's machine.

Like Edison, Maxim had but little schooling, but became a first-class mechanic and pored over such books as Ure's "Dictionary of the Arts". In middle life a short handsome man of great strength, he was as self-reliant as Ericsson and as fruitful in ideas as Trevithick and Bessemer. Traditional views were nothing to him, and, though he made himself familiar with what others had done, he looked at every problem in his own original way. He was born in the State of Maine, U.S.A., but after his visit to Europe he made his home in England, became a naturalized British subject, and in 1901 was knighted. He died on November 24, 1916, and was buried in Norwood Cemetery.

William Smith

At a meeting of the Geological Society of London on January 17, Dr. L. R. Cox, of the British Museum (Natural History), delivered a lecture on the life and work of William Smith, the Father of English geology. The subject was chosen for two reasons, one being that this was the session of the Society nearest to the centenary of Smith's death, and the second that Dr. Cox had recently had an opportunity of studying Smith's original notes, diaries and letters, which have not hitherto been made public. These MSS. have apparently lain unexamined at Oxford for many years, presumably since the death of John Phillips, Smith's nephew, who until his death in 1874 occupied the chair of geology there. They were recently discovered in Oxford in a packing-case by Prof. J. A. Douglas, the present occupier of the chair, and through his courtesy they have since been examined systematically by Dr. Cox. They are now catalogued and housed in a specially built cabinet presented by Dr. K. S. Sandford and Mr. H. A. Sandford.

There are many gaps and obscure passages in the existing records of Smith's life, and these manuscripts throw a flood of light on the activities of this great geologist. Apart from the outstanding importance of his contributions to geological science, Smith lived during the heroic age of geology. The MSS. have therefore a more than personal interest, and should contribute materially to the history of the science during this period. The only existing biography of Smith, Phillip's "Memoirs of William Smith, LL.D.", has long been out of print and is almost unprocurable. With the new material at his disposal, there is every reason for Dr. Cox to prepare a full-dress account of the life and work of so worthy a subject, and it is to be hoped that its publication may not be unduly delayed.

Treasury Grant to Universities

It has been decided to maintain the Government Grant to the Universities and Colleges at the existing level, namely, £2,149,000. In reply to a question in the House of Commons on February 20, Sir John Simon said: "The Government are fully conscious of the vital part played by the universities in the life of the community, and of the importance of maintaining the standards of university education as far as possible in the strained conditions of war. Moreover the universities are making an essential contribution to the national effort at the present time in supplying personnel of the educational standards necessary for many national services, as well as in affording more direct assistance to a number of Government Departments by means of particular researches, the provision of specialized technical equipment in laboratories, and in other ways. I have satisfied myself, after considering the representations of the Vice-Chancellors and the results of a survey of university finance carried out at my request by the University Grants Committee, that the maintenance during the coming financial year of the present provision is necessary if the universities are to continue to make their contribution to the national effort, and the Government therefore earnestly hope that local authorities will take similar action."

British and French Scientific Co-operation

In connexion with the recent visit of the French scientific delegation, Capt. D. F. Plugge, chairman of the Parliamentary and Science Committee, asked the Minister of Supply what arrangements had been made for regular liaison between French scientific representatives and the Advisory Council on Scientific Research and Technical Development. Mr. Burgin made the following written reply: "Regular liaison between the Advisory Council referred to and French scientific representatives is effected through the Mission Scientifique Franco-Britannique, which has a permanent Secretary resident in London, who will shortly be located in the Ministry of Supply. The Mission has contact with the whole of the French war-time scientific organization. There is, in addition, a direct link between the Ministry of Supply and the French Ministère de l'Armement, which can be used by the Advisory Council for matters relating to scientific inventions, in the form of a Ministry of Supply officer who has been appointed liaison officer in the French Ministère and will shortly take up his duties in Paris."

Physics in War

A SERIES of public lectures on the "Background to Present-Day Problems" has been arranged in the University of Birmingham. The second lecture in this series was given by Prof. M. L. E. Oliphant, Poynting professor of physics in the University. His subject was "Physics in War". Prof. Oliphant stressed the value of academic science, which in present circumstances can be turned to practical use. Future development of industry depends on the academic development of science, which in Great Britain is conducted only in the universities. It is therefore essential that the country should encourage academic research in science if we are to keep any sort of supremacy in industry. So far, the War has been almost entirely a physicists' war, waged with weapons depending for their operation on knowledge gained by physicists.

Prof. Oliphant referred to the great value of the pioneer work done by Dr. Lanchester in aviation, to the work of Sir William Bragg and Lord Rutherford on the detection of submarines, and to the development of the high-class optical industry. 'Wireless' is proving to be the fundamental controlling factor in the present War, and perhaps, when it is over, the public will realize how great is the work done by physicists in this field. The control of the magnetic mine presents no difficulties to the physicist. Scientific and technical men sometimes complain that they have not been given any job, and that their talents are not being used. Some of this criticism is justified, Prof. Oliphant said, because in England there is a tendency to allow administrative offices to be filled only by persons with non-technical qualifications. He deplored the conclusion that is sometimes reached that because a man has technical qualifications he cannot discharge administrative duties.

Censoring Scientific Journals

IT is announced that, at the request of Sir Walter Monckton, director-general of the Press and Censorship Bureau, Sir William Bragg, as president of the Royal Society, has undertaken the formation of a scientific panel to assist the bureau in arranging the censorship of papers in scientific journals. The following have agreed to serve on the panel: Prof. C. R. Harington (biochemistry), Prof. V. H. Blackman (botany and agriculture), Prof. A. C. Egerton (chemistry), Dr. H. L. Guy (engineering sciences), Prof. P. G. H. Boswell (geology), Prof. S. Chapman (mathematics), Dr. C. H. Desch (metallurgy), Dr. C. G. Darwin (physics), Prof. A. V. Hill (physiology), Prof. F. C. Bartlett (psychology), Prof. W. W. C. Topley (bacteriology and pathology), Prof. M. Greenwood (statistics), Sir Guy Marshall (zoology).

Animals and Plants of Use to Man

THE British Museum (Natural History) is now open to the public on Saturdays and Sundays from 1 p.m. until 4 p.m. A special exhibition has been arranged in the Shell Gallery to show the animal and plant sources from which some useful commodities come. This is too vast a field for the exhibition to be an exhaustive one, consequently only selected exhibits, illustrating commodities which lend themselves to attractive demonstration, are shown. These include the sources of certain textiles like linen, cotton, silk and rayon; plant and animal dyes used in commerce; the colouring matter and ingredients of cosmetics; the sources of leathers and of bristles for brushes; the plants and animals which produce oil in large enough quantities for it to be valuable to mankind; and some of the uses of moulds and mushrooms. Several of the cases have a war-time interest; for example, animals of use in war, margarine, bacon pigs, pests of stored food. The object of the exhibition is to show the sources of certain commodities, and not to give a detailed explanation with examples of how the raw materials are worked up into the finished products.

Discovery of a Royal Tomb in Egypt

A FURTHER discovery reported from San-el Hagar, the ancient Tanis, in the Nile Delta, promises results of even greater interest than those anticipated from the examination of the remarkable gold and silver sarcophagus discovered on this site by Prof. E. Montet, of the University of Strasbourg, in March of last year (see NATURE, 143, 512 and 552). When Prof. Montet returned to Egypt about a month ago to reopen his season's work on the tombs of the Twenty-first and Twenty-second Dynasties on this site, he proposed to examine the sarcophagus which had been left unopened. The cartouche of Pharaoh Psussenes, identified with Sheshonk, had led to the attribution of the sarcophagus to that monarch; but in the course of the work of further examination, another tomb, it is reported (*The Times*, February 20) has been brought to light, which is thought to be the royal tomb, while the gold and silver sarcophagus is now said to be that of a royal priest. The newly discovered tomb contains a huge granite sarcophagus and a profusion of funerary ornaments. These consist for the most part of gold vessels, and include a gold cup in the form of a lotus, which is said to be of great beauty. This is the first royal tomb of the period (*c.* 1100–1000 B.C.) to be discovered; and it is of enhanced importance as belonging to a phase of Egyptian dynastic history of which archæologically too little is known.

Statistical Methods and Ethnographical Observations

A NUMBER of attempts have been made from time to time to introduce statistical methods of analysis in the study of ethnographical facts, but certain obvious difficulties, more especially the artificial abstraction and the divorce of so complex an entity as an ethnographical fact from its cultural context, as a rule have militated against extended and continued application of these methods. Anthropologists, therefore, have watched with considerable interest the work of the Culture Element Survey of Native North-West America of the University of California, of which Prof. A. L. Kroeber is director. This survey was initiated as a result of an attempt to apply statistical methods of analysis to the recorded ethnographical data concerning the Indians of California by S. Klimek, who went to the University in 1933 as a Rockefeller Fellow.

The Survey has now become the most considerable example extant of the application of statistical technique to ethnographical observation. Prof.

Kroeber, in a progress report covering the work of the Survey to April, 1939 (*Anthropological Records*, 1: 7, Culture Element Distributions, 11, 1939, University of California Press), records that between 1934 and 1938 twenty trips to indigenous groups of peoples were made by 13 different observers, who brought back 279 filled-in lists of elements. In these there are now at least half a million of particularized and localized items of cultural fact, or if the supplemental notes are included, the number may well be nearer a million. Although several monographs already have been published, the great bulk of this material awaits computation. Not only does this task seem beyond human capability as a practical method of comparative ethnographic study, but also Prof. Kroeber now records that experience in the field, as well as in the study, counsels a reversal of method, at least to a major degree, in a return to the observational records of the more orthodox ethnographer.

Anglo Soviet Journal

THIS new journal has been started with the purpose of supplying "the more scientifically skilled and specialized workers in the British Commonwealth with a regular flow of information, accurate and reliable, on the progress and developments that are being realized in the U.S.S.R., in their own field, the field which they understand best". Very wisely the first issue is largely devoted to accounts of exhibitions, particularly of the great Agricultural Exhibition held in Moscow last summer, which was unquestionably the most magnificent effort of its kind the world has ever seen. Dictatorships are based on propaganda, and the Russians are the acknowledged leaders of the world in this new art. The design of the Exhibition was coherent and logical: the products of each region were brought together into separate pavilions, and each of the chief products had also its own special arrangements for show. The architecture was impressive and striking: no one could possibly forget the huge statue at the gate or the tower just inside, or the beauty of some of the pavilions.

The visitors included parties of peasants, some in picturesque local costume from all parts of the Union; many of them saw their own photographs hung up as good workers who had achieved more labour days than their fellows. More attention was paid to records than to average performances. Special notice was given to the effort of two farm workers, Okhota and Chalova, in getting forty-one tons of sugar beet per acre (the average for England and Wales is about ten tons). How far the Exhibition reflects actual performance in the countryside cannot be determined, as no detailed statistics of yield or total production have been published so far as we know since 1935, though there are some figures for the bumper year of 1937: but that is not the question. A forecast is given of the results anticipated from the proposed Trans-Volga irrigation scheme which, if it matures, and is free from too much complication of water-logging and salt, should produce food in a region where but little is grown now.

France's Colonial Problems

IN an address on "The Establishment of an Imperial Economy" (*Bull. Soc. d'Encouragement pour l'Industrie Nationale*, October 1939), M. E. du Vivier de Streel discusses the dependence of France on her colonial resources. He stresses the importance of science and technology in colonial development and the necessity of placing larger resources at the disposal of scientific organizations and technical men for the investigation of colonial problems, whether in improvement of agriculture, the prevention or control of disease, or the opening up of mineral resources. Such work should not be left precariously at the mercy of any local drive for economy. M. du Vivier de Streel refers also to the importance of population questions, education and a policy of public works, but while covering briefly much the same ground as the "African Survey" of Lord Hailey, he makes no reference to that outstanding work.

Studentship for Psychical Research

TRINITY COLLEGE, Cambridge, has established a studentship for the study of psychical research, out of a bequest left to the College for that purpose by Mr. F. D. Perrott as a memorial to F. W. H. Myers. Psychical research is defined, for this purpose, as "the investigation of mental or physical phenomena which seem *prima facie* to suggest (*a*) the existence of supernormal powers of cognition or action in human beings in their present life, or (*b*) the persistence of the human mind after bodily death". The studentship is open to any person who shall have completed his or her twenty-first year at the time when the election takes place. The studentship is tenable for one year, but a student may be re-elected once, but not more than once. The studentship will be of such value, not exceeding £300, as the electors may award after considering the nature of the research which the candidate proposes to undertake. Further information can be obtained from Prof. C. D Broad, Trinity College, Cambridge.

January Earthquakes Registered at Kew

DURING January 1940 thirteen earthquakes were well registered by the seismographs at Kew Observatory. The largest of these were on January 6 at 14h. 23m. 2s. and January 17 at 1h. 33m. 24s., though a doubtful phase preceded this at 29m. 35s. This latter shock was registered at De Bilt (Holland) at 33m. 16s. G.C.T., and the shock of January 26 was also well observed there. The United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association has determined the epicentre of the earthquake of January 6 to have been lat. 22° S., long. 170° E. with initial time 14h. 3·4m. G.C.T. This determination was based on observations of seismograms obtained at Georgetown, Sitka, Apia, Honolulu, Pasadena, Fordham, San Juan and Manila. The provisional epicentre was in a well-known seismic zone of the Pacific Ocean to the east of the island of New Caledonia. The earthquake of January 17 was found by the same authority on the basis of reports from nineteen observatories to have been provisionally centred at lat. 17° N., long. 148° E., and to have had initial time 1h. 14m. 53s. G.C.T. This epicentre was in the Pacific Ocean to the east of Zealandia Bank (Marianas Islands).

The Night Sky in March

The time of the spring equinox is March 20 18h. when the sun enters the sign Aries. The moon is new on March 9 and full on March 23. Lunar conjunctions with the planets occur as follows: March 11d. 8h., Jupiter: 12d. 14h., Saturn: 12d. 23h., Venus: 14d. 0h., Mars. It will be seen from these times that the grouping of the bright planets is still a conspicuous feature of the western sky after sunset, although Jupiter is being lost to view as the month proceeds. On March 8d. 14h., Venus is in conjunction with Saturn, and on March 26d. 14h. with Uranus. Mars is in conjunction with Uranus on March 16. Neptune is in opposition on March 14, the distance from the earth being 2,716 million miles. The constellations of bright stars associated with winter evenings are now well westwards when the sky darkens after sunset. The regions of the sky which follows—Leo, Virgo, Ursa Major and Bootes—though less spectacular to the unaided eye, are of great interest on account of the rich fields of extra-galactic nebulæ. With small or moderate optical aid, there is also a number of interesting double stars well worth examining, including Castor (separation of components 3·6″), γ Leonis (4·0″), ξ Ursæ Majoris (1·7″), γ Virginis (5·7″), ζ Ursæ Majoris (14″) and ζ Herculis (1·1″). The last binary has a period of about 35 years and was discovered in 1782 by Sir William Herschel; the greatest separation of its components is 1½″. Under favourable conditions the Zodiacal Light may be seen after sunset during this month. On fine evenings when the moon is absent, it is also worth while looking for auroras, for in March occurs one of the semi-yearly peaks in auroræ frequency. [All times are given in Universal Time; subtract 1 hour from Summer Time.]

Announcements

The University of Oxford has decided to confer the honorary degree of D.Sc. on Dr. E. V. Appleton, formerly Wheatstone professor of physics at King's College, London, and Jacksonian professor of natural philosophy in the University of Cambridge. Dr. Appleton is now secretary of the Department of Scientific and Industrial Research.

Prof. A. L. Mellanby will deliver the Thomas Lowe Gray Lecture of the Institution of Mechanical Engineers on March 15, at 6 p.m. The title of the lecture will be "Fifty Years of Marine Engineering".

The Herbert Jackson Prize for 1939 of the L.M.S. Railway has been awarded to Mr. H. I. Andrews, of the Engineering Section, Research Department, Derby, for his paper entitled "The Development of a Refrigerating Machine for Use on Trains".

The council of the Institution of Naval Architects has awarded the Premium of the Institution for the year 1939 to Mr. A. Nicholls, for his paper "The All-Welded Hull Construction of H.M.S. *Seagull.* The Wakeham Prize for 1939 has been awarded to Mr. A. Emerson, for his paper "The Effect of Shape of Bow on Ship Resistance (Part 2)".

Dr. Warfield T. Longcope, Baltimore, has been elected president of the board of directors of the Rockefeller Institute of Medical Research in succession to the late Dr. Charles R. Stockard.

The Alfred Denker Foundation Prize for 1939 has been awarded by the German Otorhinolaryngological Society to Dr. Lotar v. Hofmann, of Vienna, for a work on the influence of diseases of the ear and upper respiratory tract on the development of the infant and young child.

The Committee of the Physiological Society which was planning the Seventeenth International Congress of Physiology at Oxford in August 1941 under the presidency of Sir Charles Sherrington has decided, with regret, that the Congress must be postponed. Arrangements for the future will be made in consultation with the Permanent International Committee.

The Central Association for Mental Welfare, in co-operation with the University Extension and Tutorial Classes Council, will, if sufficient applications are received, hold a course on mental deficiency at the London School of Hygiene, Keppel Street, W.C.1, from April 8 to 20. The lecturers will include Dr. A. F. Tredgold, Dr. Henry Herd and Miss Lucy Fildes. Further information can be obtained from Miss Evelyn Fox, c/o University Extension Department, at the School of Hygiene.

A research scholarship of the value of £250 a year and tenable for two years has been founded by the Wrought Light Alloys Development Association to encourage and facilitate research in the application of light alloys to ship construction. The scholarship will be administered by a committee of the Institution of Naval Architects, and it is hoped to make the first award in September 1940. Full particulars of entry, which closes on July 31, can be obtained from the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

A prize of £20 with a diploma is awarded annually by the Council of the Royal Asiatic Society for an essay on some selected subject. The object is to encourage interest in the history and civilization of the East among non-Asiatics. In order to increase the basis of interest, the Council has decided to offer alternative subjects for the next competition. The two subjects are: (i) "Compare briefly the British, French and Dutch Systems of Administration in the East"; (ii) "The Development of Modern Turkish Literature". An essay on either subject may be submitted, and must be in the hands of the secretary at 74 Grosvenor Street, W., by October 1 next.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

In the present circumstances, proofs of "letters" will not be submitted to correspondents outside Great Britain.

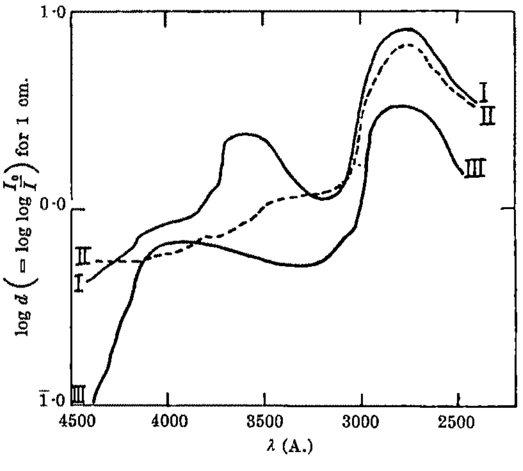
Photo-Oxides of Carcinogenic Hydrocarbons

In a recent note under the above title[1], Prof. J. W. Cook described a number of water-insoluble peroxidic photo-oxides derived from carcinogenic hydrocarbons. Experiments made in Cambridge during the past year indicate that a photochemical oxidation product, which is different in character both from those prepared by Cook and from the alkali-soluble materials prepared by Boyland, can be obtained from 3 : 4-benzpyrene under suitable conditions. 10 c.c. of a 0·1 per cent solution of the hydrocarbon in benzene (B.D.H., 'Specially Pure') is irradiated for one hour in an open Petri dish placed three inches below a neon-sensitized mercury lamp of the type described by Melville[2], nearly all the energy radiated from which is concentrated in the 2536 A. resonance line. The remaining benzene is quickly evaporated off in a current of air, and the dry residue is extracted with 10 c.c. of glass-distilled water or with weak alkali ($M./500$ $NaHCO_3$) and filtered. The resulting solution is colourless—unlike the solid residue—and its absorption spectrum, I, contains two very well-defined bands, with maxima of intensity at about 3600 A. and 2760 A. respectively. When the aqueous solution is allowed to stand, the band at 3600 A. disappears, while that at 2760 A. becomes less intense, in the course of 3–4 hours, II. The spectrum is not of the dihydroanthracene type such as is that, for example, of the water-soluble endosuccinate derivative of 1 : 2 : 5 : 6-dibenzanthracene. It indicates, however, that a labile water-soluble photo-oxidation product can be prepared from 3 : 4-benzpyrene, even though this compound gives no photo-oxide of the peroxidic type. Schulman and Rideal[3] have shown that the labile constituent of the aqueous solution can be adsorbed readily on to protein monolayers. These observations may be correlated and compared with the experiments on the photodynamic activity of the hydrocarbons described by Mottram[4].

Benzene, irradiated under identical conditions, yields a small quantity of an oily residue which dissolves freely in water to give a clear yellow-coloured solution. The absorption spectrum of this solution, III, also contains a well-defined band at 2760 A.; but this is now associated with a very wide band the maximum of which is at about 3950 A., and the absorption curve passes through a *minimum* at 3600 A. This material cannot be identified with any of the usual impurities in benzene. The same result was obtained with highly purified specimens (i) obtained from the Bureau d'Etalons Physico-Chimiques in Brussels; (ii) prepared by the method described by Lowry and Allsopp[5]; and (iii) from B.D.H., 'Specially Pure', as used for the irradiation of 3 : 4-benzpyrene.

In preliminary experiments, embryonic chick heart has been grown for two passages (4–6 days) in a medium composed of fowl plasma and chick embryo extract to which had been added either (*a*) the aqueous extract from irradiated 3 : 4-benzpyrene, or (*b*) the aqueous extract from irradiated benzene. A high percentage of the mitotic cells in series (*a*) was abnormal, and prophase was prolonged, as compared with control cultures or with series (*b*).



(I am indebted to Dr. A. Glücksmann for making the cytological examination of these cultures.) It is concluded that the labile product from 3 : 4-benzpyrene may have high biological activity, and experiments to isolate the substance, to elucidate its chemical and biological nature and to determine the part played by the benzene solvent in its production, are in progress.

I am also indebted to Prof. E. K. Rideal and to Dr. H. B. Fell for much valuable advice and assistance.

Some Properties of Laccase from the Latex of Lacquer Trees

WE have previously shown[1] that laccase, the oxidizing enzyme present in the latex of the Indo-Chinese lacquer tree (*Rhus succedanea*), is a copper-protein compound. Our purest preparation of this enzyme, which catalyses the oxidation of polyphenols and diamines, contained 0·154 per cent copper and 6·45 per cent nitrogen, corresponding to about 45 per cent protein. The remaining fraction of the preparation was composed of a polysaccharide. This preparation had a strong blue colour which disappeared reversibly on the addition of reducing substances or substrates and irreversibly on heating the enzyme to about 60° C. or acidifying it.

It was, however, impossible to ascertain whether this deep blue colour was due to a special combination between the copper and the enzyme protein or to a colouring substance present in our preparations.

In order to determine the relationship between the colour and the enzyme we have made an attempt to obtain and study this enzyme from other sources such as the latexes of the Japanese and Burmese lacquer trees (*Rhus vernicifera* and *Melanorrhœa usitata*). As a result of this study we are now able to state that the laccases obtained from all three sources are copper-protein compounds and that the blue colour of all these enzyme preparations is not due to the copper but to the presence in these preparations of a blue pigment, the nature of which is under investigation. Although we have been unable to obtain an active enzyme preparation free from the blue pigment, the latter can be easily obtained completely free of copper and protein but always mixed with carbohydrates. The pigment preparation separated from the enzyme can be reversibly reduced to its leuco compound and irreversibly decolorized by strong acids and by boiling. The facts that the blue pigment of an active enzyme preparation is much more sensitive to acids and to heating than the free pigment, and that a colourless enzyme preparation could not be obtained, suggest the possibility that the pigment is in some way connected with the normal activity of the enzyme. It is, however, impossible to say without further study of the problem whether the pigment is intimately bound to the enzyme molecule as an additional prosthetic group or is bound to a carbohydrate and acts as a carrier between the enzyme and certain substrates. The purest laccase preparation we have so far obtained contains 0·24 per cent copper and is still of a deep blue colour.

Although laccase shows a very wide range of activity, extending to a great variety of *ortho-* and *para-*phenols, diamines and aminophenols, it does not catalyse the oxidation of monophenols such as *p*-cresol. This peculiar property of laccase preparations suggested at first that these preparations are devoid of an additional factor essential for this reaction and present in crude extracts of mushrooms or potatoes. It was, however, a matter of some surprise to us to find that the addition of such crude extracts to laccase preparation not only fails to reactivate it in relation to *p*-cresol, but also that the crude extract itself in presence of laccase loses its ability to catalyse the oxidation of this monophenol.

This peculiar inhibitory property of laccase preparations can only be ascribed to laccase itself and not to some additional factor present in the preparation. In fact, this property is not affected by dialysis, it is absent in blue pigment preparations devoid of laccase and it disappears from laccase preparation on boiling or after any other treatment which destroys the enzyme.

Inactivation of Prolactin by Treatment with Phenyl *Iso*cyanate

PHENYL ureido derivatives of serum albumin peptone[1], plastein[2], and native proteins[3], have been prepared by treatment with phenyl *iso*cyanate. This reaction is eminently suitable for masking the free amino groups of protein molecules without doing further damage, since the reaction conditions are very mild (0° C. and *p*H 8). Hopkins and Wormall[3] concluded that phenyl *iso*cyanate reacts only with the free amino groups of the lysine components of the protein molecules.

In view of reports that prolactin, the anterior pituitary hormone which stimulates the pigeon crop-gland, can be inactivated by acetylation with ketene[4], and treatment with nitrous acid[5], we were led to compare the crop-stimulating activity of prolactin with that of its phenyl ureido derivative.

Phenyl ureido prolactin was prepared by treating a solution of purified prolactin from ox pituitary with phenyl *iso*cyanate at *p*H 8 and 0°, diphenyl urea from excess phenyl *iso*cyanate being removed by centrifuging. The pigeon crop-gland stimulating activities of this and a control solution were estimated by Rowlands'[6] systemic method.

Test liquid	No. of birds	No. of daily injections	Volume injected (ml.)	Mean $\frac{\text{crop wt.} \times 100}{\text{body wt.}}$
Prolactin	9	6	1	1·12
Phenyl ureido prolactin	10	6	1	0·45

The results in the accompanying table show that destruction of the free amino groups by reaction with phenyl *iso*cyanate has resulted in a very marked loss of activity. The percentage inhibition (see Folley[7]) was approximately 87. The observations of Evans and his co-workers[4,5], that the crop-stimulating activity of prolactin depends on the presence in the molecule of free amino groups, appear therefore to be confirmed. These experiments are being continued.

Hyperprothrombinæmia During Pregnancy

THE determination of prothrombin in blood plasma acquired especial importance after the discovery[1] of vitamin K, which is known to play a certain part in the formation of prothrombin. During my researches on the normal and pathological variations of prothrombin I have found the concentration of prothrombin in pregnant women to be remarkably high, a condition not formerly known.

The determination of prothrombin in plasma has been carried out according to a method recently indicated by me[2]. My method differs from those of others in that the prothrombin is determined in relation to a standard prothrombin solution. It has proved justifiable to take the blood plasma of the investigator as a standard solution. By means of this method the prothrombin values of 104 normal persons of both sexes have been determined. If the average value is put at 100, the distribution has been found to range from 82 to 118 with a standard deviation of 6·58.

The results of the determinations of prothrombin in pregnant women are seen in the accompanying table. The figures indicate the average prothrombin value in the women examined.

Month of pregnancy	Number of subjects	Average prothrombin value
1–2	7	105
2–3	8	111
3–4	7	123
4–5	5	136
5–6	4	149
6–7	7	146
7–8	5	152
8–9	27	169

It is apparent from this table that the average prothrombin values of all pregnant women examined after the third month of pregnancy are considerably higher than the average value of the normal material and exceed the highest values observed in the latter. The figures indicate a steady rise from the third month until the end of pregnancy.

One month after delivery, normal prothrombin values are found.

The significance of hyperprothrombinæmia in pregnant women will be further elaborated in a forthcoming publication.

Interferometric Serum Test for Cancer

A PRACTICAL optical test of the blood serum that appears to prove of assistance in the early diagnosis and prognosis of cancer is here described, the validity of which has been ascertained in a few hundred clinical cases.

The test involves the measurement of the densities of a certain number of samples of the person's blood serum, by the use of an interferometer. The density to be determined is the result of interaction between an extract of cancer cells and the serum under examination.

Previous studies leading up to the test were those of Dr. Ernest Freund and G. Kaminer[1], F. Neuberg and A. Waterman[2], further refined by Drs. R. Willheim and K. Stern[3]. The first four investigators claimed to have established the following facts: A lysis of cancer cells takes place in the blood serum of non-cancerous persons. Serum of cancerous persons has not only no lytic substance but even a substance which protects cancer cells from destruction.

Willheim and Stern, however, stated that a diagnosis of carcinoma could not be made merely by determining the presence or absence of any specific cancer-destroying substance. They postulated the existence of cancer-destroying and cancer-protecting chemical principles in the serum, the difference in the balance of which determined whether or not a serum could be clinically associated with carcinoma.

It seemed that a surer and simpler diagnostic reaction should be obtained by using an extract of human cancer cells instead of the whole cells. An alcoholic extract of carcinoma of the breast, because of its convenience of freedom from infection, was prepared to serve as the testing agent. Four test tubes are set up. Into each of these is pipetted the same amount of cancer extract, 0·05 c.c. Next, the serum to be tested is added in each tube in increasing amounts, 0·05, 0·25, 0·5 and 1·0 c.c. respectively. Thus four grades of dilution of the extract with the serum are established. The tubes are then incubated at 37° C. for 12 hours. Serum is then added to the first three tubes until the level is the same as for the fourth test tube. All tubes are carefully shaken and allowed to settle in a refrigerator for six hours.

Interferometer readings are made to obtain the densities of the four dilutions of the extract with the serum. The pattern of the readings plotted out graphically shows a characteristic difference between the cancerous and non-cancerous sera.

Compared with the pattern of the four interferometric readings of normal serum, that of the cancerous serum shows a 'disturbed balance' between the cancer-lytic and cancer-protective properties.

A cancer curve slowly changes to a normal curve after successful operation. It changes again from a normal to a cancer curve in the earliest stages of recurrence. A cancer curve does not change post-operatively if metastases have already taken place or are about to take place elsewhere in the body.

The test reaction failed to appear when serum of a pregnant woman or of a person with tuberculosis, syphilis or numerous other diseases was used. However, as was to be expected, fever and intensive X-ray treatments influenced the serum so as to make the test uncertain. Extract of normal organs, for example, fibroid tissue, failed to show any reaction.

This preliminary report deals with 325 cancer cases in which the test was proved to be 96 per cent correct. Altogether 575 cases have been tested.

A Vacuum Core-Sampler for Deep-Sea Sediments

FEW geophysical problems have such important bearings as that of sampling undisturbed sediment cores of great length from ocean deeps. Questions pertaining to the permanence of ocean basins or their subsidence, to continental drift, to climatic changes and to variations in volcanic activity, etc., can best be answered through studies of the stratigraphy of deep-sea sediments, sampled in the manner just indicated. Recently, Dr. Piggot of the Carnegie Institution of Washington has obtained cores from the north-west Atlantic bottom approaching 3 m. in length, by projecting the sampler into the sediment by means of an explosive charge.

According to a scheme advanced by one of us at the meeting of the International Council in 1933, the hydrostatic pressure prevailing at great depths has been utilized for forcing a tube-sampler down into the sediment. The first instrument, constructed during last summer in the workshop of this Institute and put to practical tests in the fall of the same year, consisted of a 2 m. length of steel tubing, 2 in. wide, closed at its upper end and having a water-tight piston at its lower end, released by trigger action as soon as it touched the sediment surface. The air was pumped out of the tube before immersion, so that the piston, followed by a column of sediment, was able to move up to the upper end without compressing any air behind it, which might otherwise expand and push out the core on hauling up the sampler to the surface. The tests made with this first sampler proved the release to function well, and the tube was filled with sediment; but at depths exceeding 150 m. the shock due to the impact from the piston proved too severe for the steel bolts securing the lid to the upper end of the tube. Moreover, the looser kinds of sediments were sucked into the tube, before it had time to descend completely into the sediment.

A modified instrument was accordingly constructed with a cylindrical container of much wider bore attached to the upper end of the tube. The container is evacuated, whereas the tube itself is completely filled with water which, after the release, is free to enter the container through a nozzle of a more or less narrow bore, according to the depth in which the sample is to be taken. Thus the rate at which the tube sinks into the sediment can be made practically equal to the rate at which the sediment core mounts into the tube. Tests with this new sampler made at depths down to 240 m. have been entirely successful, cores of lengths varying between 160 cm. and 200 cm. being readily obtained. Markings on the outside of the tube proved the sampler to have sunk into the sediment to a depth agreeing to within a few centimetres with the length of the core. A deep-sea sampler with a larger spherical container and a tube 6 metres in length is now being constructed and gives hope of obtaining cores of approximately the same length from depths of 4,000 m. or more.

With all types of samplers hitherto used, including that of Dr. Piggot, the friction against the inside of the tube prevents cores of equal length to the depth of immersion in the sediment being sampled (see Pratje's recent experiences in the Baltic). With the vacuum sampler this friction is counteracted by suction, properly regulated, so that the core will give a true picture of the undisturbed stratification of the sediment. Moreover, since the force pressing the tube down into the sediment increases with the bore of the tube, and with the depth of water, it should be possible to obtain cores of still greater thickness and length, say 10 m. if not even more, by means of this sampler. The instrument will be described in greater detail in a coming issue of *Meddelanden från Oceanografiska Institutet i Göteborg*.

The α, β Transformation of Quartz

Sir C. V. Raman and T. M. K. Nedungadi have discussed in NATURE of January 27 a remarkable series of photographs showing the spectrum of monochromatic light scattered in a quartz crystal at various temperatures up to 530° C., not far from the transition point at 575° C. Their results are of special interest to me because they serve to confirm my opinion that, at any transition temperature (including the melting point), some kind of resonance occurs between two frequencies which characterize the two phases concerned. In other words, the transition takes place when there is close agreement between a frequency characteristic of the first phase and another frequency characteristic of the second phase. Since resonance may occur when this agreement is not quite exact, an explanation is possible of the fact that for many substances the 'setting' point is not quite the same as the 'fusion' point.

In the experiments on quartz, the authors state that "the 220 cm.$^{-1}$ line behaves in an exceptional way, spreading out greatly towards the exciting line and becoming a weak diffuse band as the transition temperature is approached. On the other hand, the other intense lines [including 132 and 468 cm.$^{-1}$] having both larger and smaller frequency shifts continue to be easily visible, though appreciably broadened and displaced". They infer that the binding forces corresponding to the line 220 cm.$^{-1}$ diminish rapidly with rising temperature, and also that the increasing excitation of this particular mode of vibration and the resulting deformation of the atomic arrangement are in a special measure responsible for the changes in the physical properties of the crystal, as well as for inducing the transformation from the α to the β form.

So far as I am aware, there is no information available as to the characteristic frequency of β-quartz save that which is obtainable from the Sutherland-Lindemann formula

$$\nu = \frac{3 \cdot 08 \times 10^{12}}{V^{1/3}} \sqrt{\frac{T}{M}},$$

where T is the absolute temperature of the melting point, M is the molecular weight, and V is the molecular volume. Assuming that T is 2,053° K., and the density is 2·65, the calculated frequency is $3 \cdot 63 \times 10^{12}$ sec.$^{-1}$, corresponding to 212 cm.$^{-1}$, and thus supports the hypothesis put forward.

For some time I have been examining the effect of substituting the absolute value of a transition point for T in the melting point formula, and have obtained interesting results. Taking 848° K. as the transformation temperature of α, β-quartz, the corresponding frequency is $4 \cdot 09 \times 10^{12}$ sec.$^{-1}$ or 136 cm.$^{-1}$. This is very nearly the same as the Raman line 132 cm.$^{-1}$.

The two suggestions which I wish to emphasize are these: (1) the occurrence of a transformation is associated with some kind of resonance between approximately equal frequencies characteristic of the phases concerned; (2) the applicability of the Sutherland-Lindemann melting point formula to the transition point.

Chemical Action of γ-Radiation from ^{80}Br

DURING the course of an investigation into the exchange of radiobromine between a number of organic and inorganic bromides, it has been observed that with certain of the latter, for example, aluminium bromide, and a wide variety of organic bromides, a complete exchange of all the bromine atoms in the system takes place very quickly at room temperature. With many other inorganic bromides, however, there is apparently no exchange, but an *extraction* of the 18-min. ^{80}Br isotope from the radioactive organic bromide.

For example, if inactive antimony tribromide be dissolved in radioactive ethyl bromide several hours after the preparation of the latter, that is, when all the 18-min. isotope originally present has decayed, and immediately after the dissolution the ethyl bromide be volatilized away *in vacuo*, the residue of antimony tribromide is found to be strongly radioactive, with a half life of 18 min., the 4·5- and 36-hour periods being found in the condensed ethyl bromide.

That is, the antimony tribromide has made a selective extraction of the short-lived radiobromine isomer which has grown from, and is in transient equilibrium with, the parent 4·5-hour ^{80}Br. This result is to be attributed to a form of intramolecular photo-dissociation of the ethyl bromide by the internal conversion of the γ-ray which, as Snell[1], Abelson[2] and others have shown, is emitted by the bromine nucleus during the isomeric transition. A similar extraction was observed with arsenic tribromide, phosphorus pentabromide and, though the amount extracted was less, with crystals of mercuric bromide and of potassium bromide, and with metallic silver, mercury and even gold. In each case the radiobromine extracted was almost pure 18-min. ^{80}Br, the 'tail' to the decay curve due to the longer-lived isotopes being very small—generally less than 1 per cent of the total initial activity.

Segré, Halford and Seaborg[3] obtained a partial separation of the radiobromine isotopes by the precipitation of silver bromide from an aqueous methyl alcoholic solution of radioactive *tert*-butyl bromide, and DeVault and Libby[4] obtained a more complete separation by the precipitation of silver bromide from a radioactive bromate solution. These authors attributed the separation to a chemical activation of the molecule containing the bromine, by the recoil from an internal conversion electron. LeRoux, Lu and Sugden[5] have also found that a greater proportion of the 18-min. isomer than of the 4·5-hour isomer can be extracted by aniline from neutron irradiated ethylene dibromide, or by water from a benzene solution of a radioactive alkyl bromide, and offer as explanation[6] that the soft γ-ray gives a recoil which can only activate, but not disrupt, the C–Br bond.

The present results indicate, however, at all events in the case of ethyl bromide, that the process is not simply a matter of supplying an extra activation energy (over that received spontaneously by thermal agitation) to an otherwise exothermic reaction, since the removal of a bromine atom or ion from an ethyl bromide molecule by arsenic tribromide or mercuric bromide, for example, is endothermic by a very large amount.

Moreover, the mechanical recoil of the bromine nucleus from the γ-ray or from a conversion electron cannot be a major factor in these reactions. Siday[7] has shown that the energy of this γ-ray emitted during the transition is about 43,000 e.v. The energy of recoil of the comparatively heavy bromine nucleus from such a γ-ray is about 286 cal./mol., which is less than the energy of thermal agitation of the molecule at room temperature. The internal conversion of this γ-ray results in the expulsion of conversion electrons, the recoil from which will be greater than from the γ-ray, but even with 100 per cent efficiency of recoil would be less than 7 kcal./mol. Such an additional energy would accelerate the hydrolysis of an alkyl bromide, but could not bring about the present results. These suggest that a bromine atom or ion is broken completely away from the ethyl bromide molecule before reaction, a process requiring about 60 kcal./mol. if the disruption is into neutral fragments, and rather more for disruption into ions (much of the additional energy required to form the ions is recovered as solvation energy when the process takes place in solution).

It appears more probable, therefore, that the C–Br bond is broken immediately following the nuclear transition, not by mechanical recoil of the bromine atom, but by a process involving any one of a series of excited molecular states which are produced during the gradual settling down of the bromine atom after the start of the internal conversion. That is, the molecule is broken up, not merely activated, by a process which is more in the nature of a photo-dissociation brought about by intramolecular quanta.

All these reactions were carried out with anhydrous materials at room temperature, the ethyl bromide being volatilized away *in vacuo* ($\sim 10^{-3}$ mm. mercury), at or below room temperature and condensed by liquid air. The radiobromine was converted into AgBr, the activity of which was measured with a Lauritsen type quartz fibre electroscope.

Effect of Temperature on Lubricant Films

THE friction apparatus developed by Bowden and Leben[1,2] has shown that when clean steel surfaces slide on one another, the motion is not smooth but proceeds in a series of irregular jerks. This apparatus has also been used for comparing the lubricating properties of various substances. With the high loads and low speeds employed, the conditions which obtain correspond to boundary lubrication. Experiments show that when a non-polar lubricant such as medicinal paraffin oil is used, the motion still proceeds in stick-slips, though the average value of the friction is lower than for the dry surfaces. Certain long-chain fatty acids and small quantities of these acids in a non-polar oil will, however, cause continuous sliding[1,3]. This property has been used to detect the oxidation of non-polar oils on heating. The original oil gives a jerky motion; when a certain amount of oxidation has occurred the motion becomes smooth. The rate of this oxidation becomes appreciable with most oils at temperatures above 150° C. and the change in the frictional behaviour is irreversible on subsequent cooling[3].

Some recent work on commercial oils giving smooth sliding on steel surfaces at room temperature has revealed a new effect. As the surface is warmed (to temperatures usually ranging between 40° C. and 80° C.) stick-slips set in, which increase in size with temperature and decrease as the temperature is reduced. Provided the heating has not been sufficient to cause appreciable oxidation of the lubricant, this effect is reversible. Subsidiary experiments have shown that it is not due to any change of viscosity with temperature, and the effect is to be attributed to a desorption or disorientation of the lubricant film. These results indicate that *in those cases where boundary lubrication occurs*, a lubricant which behaves well at room temperature (that is, which gives smooth sliding) may have poor lubricating properties at quite moderate temperatures of the running parts. The temperature at which this reversible effect occurs will be a measure of the strength with which the lubricant film adheres to the surface; the higher the temperature the more strongly is the film adsorbed on the surface. It is possible by such means to compare different lubricants in this respect.

Experiments have also been carried out with pure fatty acids, and similar effects have been observed, though the temperature at which stick-slips commence is appreciably higher than the values given above and increases slightly with the chain length of the acid.

These observations are of importance in any general consideration of the effect of temperature on the behaviour of adsorbed films.

I am indebted to the Asiatic Petroleum Company for permission to publish this work, which was carried out in their laboratories.

Points from Foregoing Letters

C. B. Allsopp has found that photo-oxidation products of 3 : 4-benzpyrene, which can be extracted with water or dilute alkali, possess characteristic absorption spectra. The unstable extracted material, which was shown by Schulman and Rideal to react strongly with protein monolayers, is found to produce a high percentage of abnormal mitotic cells in embryonic chick heart tissue cultures.

After examining the oxidizing enzymes, named laccases, obtained from the latex of the Indo-Chinese, Japanese and Burmese lacquer trees, D. Keilin and T. Mann conclude that they are all copper-protein compounds containing a blue pigment the nature of which is under investigation.

A. C. Bottomley and S. J. Folley find that the pigeon crop stimulating activity of the anterior pituitary hormone prolactin disappears when the free amino groups react with phenyl *iso*cyanate.

O. Thordarson finds that the prothrombin content of the blood plasma of pregnant women is higher than normal. A steady rise occurs from the third month of pregnancy until delivery; normal values are found again one month after delivery.

It is claimed by M. W. Mettenleiter that the density of blood serum incubated with an alcoholic extract of carcinoma of the breast, can be used as a test for cancer. When the observations are plotted, a characteristic difference between cancerous and non-cancerous sera is observed; this difference disappears after successful treatment and reappears with recurrence. The test fails in cases of pregnancy and of certain diseases.

The experimental results of Raman and Nedungadi on the α, β transformation of quartz are reviewed by Prof. H. S. Allen. Two suggestions are put forward: (1) at any transition temperature (including the melting point) some kind of resonance occurs between two approximately equal frequencies characteristic of the phases concerned; (2) the Sutherland-Lindemann melting point formula may be applied to the transition point.

Experiments on the exchange of radiobromine between organic and inorganic bromides are described by F. Fairbrother. The radiobromine with a half-life of 18 min. can be separated almost completely from the others by extraction of a radioactive organic bromide with certain inorganic bromides and metals. Since the energy of mechanical recoil, from the γ-ray emitted during the isomeric transition of ^{80}Br, or from its conversion electrons, is too small to break the C–Br bond or to bring about the observed reactions, these are attributed to a fission of the bond by an intramolecular photo-dissociation.

Using the stick-slip friction apparatus developed by Bowden and Leben, D. Tabor finds that certain lubricants giving smooth sliding on steel at room temperature give stick-slip motion when heated to moderate temperatures. This effect is reversible with temperature and has been observed with pure fatty acids. It is attributed to a desorption or disorientation of the lubricant film.

RESEARCH ITEMS

Facial Deformity in Anthropomorphic Pottery

It is pointed out by R. N. Salaman that in any considerable collection of Chimu Peruvian pottery there will be found among the anthropomorphic pots examples in which some peculiar deformity of mouth or nose or both occur (*J. Roy. Anthrop. Inst.*, 69, 1 ; 1939). Several different explanations have been put forward. Distinct groups may be recognized, namely, those which depict abnormal localized obesity, those in which the face is distorted as a result of facial paralysis, and those in which the mutilation is induced and associated with some representation, however conventionalized, of the potato. The potato was regarded as controlled by a spirit which was strengthened by blood libations effected by the act of mutilation. This mutilation consisted in the abscission of the upper lip, and often the lower as well and the removal of the soft parts of the nose. The effect was a startling display of teeth and a cavernous mouth, the explanation being that the Peruvians regarded a potato eye as a mouth, which indeed it resembles in the Peruvian varieties more closely than an eye. A pot of the proto-Chimu period from Chimbote shows the symbolism complete. It depicts a human figure built up from a single potato tuber, in which the end of the nose and the central portion of the upper lip are removed, while on the body are displayed potato eyes from each of which are growing several slender sprouts. In the left hand the figure holds a digging stick. A large number of the pots for funerary purposes exhibit facial deformities which might be illustrative of some disease process, such as, it is suggested, the *uta* disease due to an infection with the protozoan *Leishmania brasiliensis* in various stages, after surgical treatment and after death. The reason or reasons underlying the frequent representation by the ancient Peruvians of maimed and mutilated figures remain obscure.

Moulting in Snakes

A short paper by Robert M. Stabler, reporting upon twenty-one snakes observed for periods ranging from 11 to 47 months, adds to the somewhat meagre knowledge about this habit (*Copeia*, 227 ; 1939). The snakes belonged to seven different genera and fourteen species, and yet they showed similarity in the frequency of sloughing when account was taken of the periods of reduced activity, and when observations were confined to individuals which fed readily and were perfectly healthy. Continuous observations showed apparent dissimilarity ; thus in 47 months one specimen of *Agkistrodon piscivorus* sloughed fifteen times, while another sloughed three times in 12 months, and one individual of *Elaphe o. obsoleta* only twice in 12 months, the average periods between sloughs in these cases being respectively, 3·1, 4, and 6 months. But all the snakes were kept in a room not specially heated, and it was found that when winter temperatures fell as low as 40° F. a state of pseudo-hibernation or 'rest period' was induced, during which the snakes lay motionless for days, took food sparingly, and sloughed rarely. This period, extending from about October to April, averaged 6·4 months in the year. When the rest periods, which were carefully recorded, were omitted from the computation, the sloughing in the three cases mentioned took place respectively at intervals of 1·3, 2·3, and 1·2 months. In all the snakes the periods were somewhat similar, generally ranging around about 1·5 months.

Translocation in the Somatic Tissue

L. V. Morgan reports the finding of two salivary gland nuclei with a reciprocal translocation between the right arms of chromosome 2 and of chromosome 3 of *Drosophila melanogaster* (*Genetics*, 24, 747–752 ; 1940). The interchange must have occurred in the last or in a very late division in the nucleus of a somatic cell before the full number of cells of the salivary gland was attained. The discovery is of importance in showing that reciprocal translocations, like mutation, or crossing-over, may occur during mitosis as well as during meiosis.

Genetical Investigation in Neurospora

Neurospora tetrasperma normally has four spores per ascus, and differs in this respect from *Neurospora sitophylla*, which forms eight spores per ascus. One culture of *N. tetrasperma* was found by B. O. Dodge (*J. Hered.*, 30, 467–474 ; 1939) to form ascocarps which contained aborting and sterile asci. About 10 per cent of the ascocarps occasionally contained a fertile ascus, with usually eight not four ascospores. If these eight spores were cultured, those that germinate again produced 4-spored asci. On the other hand, a binuclear spore sometimes found in an ascus would give aborting ascocarps with an occasional 8-spored ascus, as in the original culture. It would seem that this culture of *N. tetrasperma* produced eight spores, half of which carry *E*, a lethal which prevents germination. As a result of segregation at the second division for both sex factors, *Aa* and the lethal *Ee*, a large spore may contain *AE* and *ae* in the two nuclei, and can germinate and give rise to ascocarps. Many of these will abort, but some will contain 8-spored asci, since *E* affects the nuclear distribution and spindle mechanism at spore formation.

Separation of Amino-Acids in Protein Digests

An interesting new method of protein analysis is outlined by R. L. M. Synge (*Biochem. J.*, 33, 1913, 1918, 1924 and 1931 ; 1939). The amino-acids in a digest are acetylated and then extracted with chloroform in a continuous liquid extractor. The partition coefficients of these acetylated amino-acids between chloroform and water vary so widely that separation into groups is readily accomplished, for example, acetyl-l-phenylalanine is soluble and *N* acetyl-l-hydroxyproline almost insoluble in chloroform. Subsequent benzoylation of hydroxy groups, however, produces derivatives easily soluble in chloroform such as *N*-acetyl-*O*-benzoyl-l-hydroxyproline and hydroxyamino-acids can thus be readily separated from other amino-acids. Fractionation of hydroxyamino-acids from each other may be carried out by preparing their *N*-acetyl-*O*-methyl derivatives, which have very different chloroform-water partition coefficients.

Solvent Effect on Solubility

THE solubilities of barium iodate, silver acetate and silver sulphate in dioxane-water mixtures at 25° over the complete range of solvent mixtures have been determined by T. W. Davis, J. E. Ricci and C. G. Sauter (*J. Amer. Chem. Soc.*, 61, 3274; 1939). This corresponds with a variation of dielectric constant of 2·10 to 78·55 (the widest so far reported in solubility work), and the results have been treated in the light of the interionic attraction theory and Born's theory of solvent interaction, in which the free energy of charging spheres of radius r in a medium of dielectric constant D is set equal to $Z^2e^2/2Dr$, where Z is the ionic valency and e the charge on the electron. This equation, even when corrected for interionic effects, fails to account for the variation of solubility with solvent, the predicted solubility in each case being too low. An empirical result, that the mean activity coefficient of an electrolyte in saturated solution is almost independent of the dielectric constant of the medium, is pointed out. The test of the Born equation applied was to determine whether the value of a, the effective ionic diameter, remained constant from one medium to another and was related to the solubility and dielectric constant according to an equation made up by combining Born's equation with the Debye-Hückel equation containing the simple correction for ionic diameter. This was not found to be the case. The questions of a changing with solvent and incomplete ionization of solute (for example, with barium iodate) are to some extent considered by the authors, but not the use of a more accurate equation for activity coefficients than the Debye-Hückel equation.

Chaulmoogra Oils

CHAULMOOGRA is the native name of the oil expressed from the seeds of the fruit of the *Taraktogenos kurzii*, and it has been used for centuries in Burma and India in the treatment of leprosy. The tree is widely distributed in Burma and is also found in Thailand (Siam), eastern Bengal and Assam. The gathering of the seeds is dangerous on account of wild animals, and as the fruit is no longer fresh when gathered the oil is of poor quality and is often adulterated. The name 'chaulmoogra' is also applied to any oil containing chaulmoogric acid, such as *Hydnocarpus wightiana* and *H. anthelmintica*. The latter occurs abundantly in Thailand, Cambodia, Cochin China and Laos, and has been successfully cultivated in Hawaii and the Belgian Congo; its seeds form an article of export to China, where they are known as Ta-fung-chi or Ta-feng-tzu. *T. kurzii* has also been acclimatized to Brazil. H. I. Cole and H. T. Cardoso (*J. Amer. Chem. Soc.*, 61, 3442; 1939) find that chaulmoogra oil (from *T. kurzii*) keeps for years if expressed from dried fresh seeds and not from old seeds, and is non-irritating upon injection. They give the first quantitative analyses of oils from *H. anthelmintica* and *T. kurzii*, finding that they contain hydnocarpic, chaulmoogric, gorlic, oleic and palmitic acids as well as small amounts of lower homologues of hydnocarpic acid. They also give the physical and analytical characteristics of five chaulmoogra oils. One of these (from *O. echinata*) contained no hydnocarpic acid but was very rich in chaulmoogric acid. The true chaulmoogra oil contained the highest percentage of gorlic acid.

Prehistoric Copper

AT a meeting of the Newcomen Society held at the Iron and Steel Institute on February 14, Mr. H. H. Coghlan read a paper on "Prehistoric Copper and Some Experiments in Smelting". Native copper, he said, occurs as thin plates, or in massive form in crevices in the rocks. The latter form is very intractable to work, and it was the former that prehistoric man used for making such things as needles, awls, beads and chisels. These were made by cold-working. As to the discovery of the processes of tempering, melting and smelting, Mr. Coghlan thought that at some early date, say about 5000 B.C., small objects were made by hammering; then when tempering was discovered and understood, larger objects were made, followed by, first, the discovery of smelting, and then of melting. The discovery of the process of smelting from ore must have been accidental. Some thought it was due to ore melting in a camp fire. To test this theory, the author made experiments trying to reproduce the conditions likely to have obtained, but the result was negative. Taking the green carbonate malachite, he had subjected it to the heat of a charcoal fire, but all he obtained was black oxide of copper. The result led him to try smelting the ore in an arrangement in which the conditions were such as existed in the ancient pottery kiln, and in this experiment he obtained metallic copper in the form of well-shaped crystals. Mr. Coghlan concluded by discussing the problem of how malachite may have been used in connexion with pottery.

Constants of the Star-Streams

W. M. Smart and T. R. Tannahill have utilized the photographic proper motions of 18,323 stars in the zone −40° to −52° for the determination of the constants of the star-streams (*Mon. Not. Roy. Astro. Soc.*, 100, 1; November 1939). The results of the analysis according to the two-stream theory are as follows:

	Drift i	Drift ii
R.A. of apex	88·0° ± 1·4°	303·6° ± 9·5°
Dec. of apex	−8·5 ± 0·6	−75·0 ± 13·5
Space velocities of drifts	1·463 ± 0·035	0·650 ± 0·035

The probable errors are small in the case of Drift i but they are not very satisfactory in the case of Drift ii. The vertex of the star-streaming is R.A. 271·5° ± 1·6°, Dec. −14·5° ± 2·0°, or, in galactic co-ordinates, long. 343·2° ± 1·0°, lat. −0·5° ± 1·7°. The vertex derived from the Cape proper motions is seen to lie on the galactic equatorial plane, but the longitude exceeds that derived by other methods by 16°, though it is almost exactly the same as Jackson's value. The equatorial co-ordinates of the solar apex are R.A. 265·1°, Dec. +26·1°; solar speed 0·879 astronomical unit. From the values of the stream-constants the ellipsoidal constants are calculated, and the results are compared with those obtained by Jackson from his analysis of the proper motions according to the ellipsoidal hypothesis. Those obtained by the first method are $G_0 = 334·6° \pm 1·2°$, $K/H = 0·705 \pm 0·002$, and the corresponding values found by Jackson are 343·6° and 0·59°; G_0 denotes the longitude of the vertex and K/H is the ratio of the minor axis to the major axis of the velocity ellipsoid. The authors show that a very close agreement between the two values derived by such dissimilar methods is not to be expected.

GLUTAMIC ACID OF PROTEINS

THE recent claim of Kögl and Erxleben[1] that the proteins of malignant tissues are partially racemized was based largely on the observation that the hydrolysates of such proteins, unlike those derived from normal tissues, contained glutamic acid which showed evidence of racemization, in some cases to a high degree. In our preliminary communication[2] we directed attention to the fact that we had been able to isolate the normal, unracemized, l (+) glutamic acid hydrochloride in good yield from three different samples of malignant tissue protein material, and suggested that a more extensive investigation was needed before Kögl and Erxleben's claim could be admitted. In reply, these latter workers[3], *inter alia*, produced evidence which they believed to show that our modified Foreman[4] method of analysis was unsuitable for demonstrating the presence of any racemized glutamic acid in protein hydrolysates, because the calcium salt of this acid is more soluble in 90 per cent alcohol than is that of the natural l (+) antipode, and also because the racemic hydrochloride is more soluble in either concentrated or 20 per cent hydrochloric acid than is that of the natural product.

Our own investigations have now led us to conclusions that are still at variance with those of Kögl and Erxleben, and a paper giving full details of our work has been submitted for publication in the *Biochemical Journal*. The points to which we wish to direct attention in this communication are as follow:

(1) The calcium salts of both the racemic and the l (+) glutamic acids are equally insoluble in 90 per cent alcohol, and the fact that our modified Foreman method of analysis is applicable to hydrolysates containing large amounts of the racemic acid follows from the data for the wheat protein gliadin given in the accompanying table.

Protein material	Method of analysis	Glutamic acid isolated		Yield of d(−) glutamic acid as per cent of protein
		Yield as per cent of protein	Percentage racemization	
Normal ox heart	Foreman	11·93	2·7	0·16
Normal calf lung	Foreman	8·70	1·8	0·08
Grafted sarcomata from mice	Foreman	8·34	2·7	0·11
Metastases from liver of a woman with carcinoma of colon (E.B.)	Foreman	10·28	4	0·22
Metastases from liver of a man with carcinoma of bronchus (W.V.)	Foreman	10·25	2·8	0·165
,,	Cuprous oxide: First crop	0·44	63·4	0·14
	Second crop	2·39	1	—
Gliadin	Direct as hydrochloride,	33·53	nil	—
	followed by Foreman analysis	9·55	46	2·21

(2) When the method is applied to hydrolysates containing only a small amount of the racemized acid, the first two or three crops of hydrochloride isolated will consist almost exclusively of the l (+) antipode, and it is necessary to search the mother liquors to obtain evidence for the racemized product. What we believe to be well-nigh quantitative glutamic acid analyses of three malignant tumour and of two normal tissue protein preparations are given in the table. In all five cases the yield of total glutamic acid is high, but that of the unnatural d (−) antipode is very low, and there is no apparent differentiation between the two types of tissues. It is clear from these results that our failure to demonstrate the presence of the racemized acid in our earlier tumour analyses was due to the fact that the natural l (+) antipode was present in large excess.

(3) The above-mentioned results are not in keeping with those of Kögl and Erxleben. The latter workers, using the Dakin butyl alcohol procedure, have in two instances isolated products showing a high degree (80 per cent; 89 per cent) of racemization in yields that indicate 4·16 per cent and 3·69 per cent respectively of the d (−) antipode in terms of protein material taken for analysis. Nevertheless, in the majority of their analyses they have used the shorter, cuprous oxide, method of Abderhalden and Fuchs[5], and whereas from normal tissue materials the products isolated in yields of from 1·65 per cent to 5·0 per cent showed the normal rotation, those obtained from malignant tumour materials, in yields sometimes as low as 0·34 per cent, always showed a high degree of racemization (20–85 per cent). Because they had shown that the hydrochloride of the racemic acid was more soluble in concentrated hydrochloric acid than that of the natural antipode, they have assumed that the glutamic acid they failed to isolate from the hydrolysate would be racemized to at least the same degree, and have accordingly interpreted their results as showing the presence of the d (−) antipode in amounts comparable with those obtained from the two samples of malignant tissue mentioned above.

That this is not a valid interpretation follows from the results given in the table, which show that under the conditions of these cuprous oxide analyses the racemic glutamic acid hydrochloride may be preferentially salted out, even when the l (+) glutamic acid is present in very large excess. In the case quoted, the first crop by the cuprous oxide procedure, obtained in only 0·44 per cent yield, showed 63·4 per cent racemization, yet the companion Foreman analysis, which gave an overall yield of 10·25 per cent, showed only 2·8 per cent racemization.

These findings explain the apparently conflicting results recorded in the recent literature[6] and show that the interpretation of Kögl and Erxleben's cuprous oxide analyses must be based on the *yield* of the product isolated and not on its *percentage racemization*. A review of their data on this basis suggests that, except in three cases, the amount of d (−) glutamic acid present in the various malignant tumour hydrolysates was of the same order (0·5 per cent) as we ourselves have obtained from both malignant and normal tissue material, and much less than we have obtained from seed proteins, such as gliadin and edestin. We have, moreover, isolated partially racemized aspartic acid from the hydrolysates of both types of animal tissue protein, and are thus led to conclude that racemization of amino acids is not a characteristic of malignancy.

IN 1939, Kögl and Erxleben[1] reported the isolation from tumour proteins of amino-acids of the *d*-series, chiefly *d*-glutamic acid, and developed a new theory of the origin of malignant tumours based on the view that malignant growth depends upon the alteration of the proteins in tumour cells owing to the inclusion of racemized amino-acids. Chibnall *et al.*[2] failed to detect the unnatural form of glutamic acid in hydrolysates from tumour proteins. Graff[3] was also unable to reproduce Kögl's results. According to Kögl[4], the failure of these authors to obtain *d*-glutamic acid was due to the fact that they used a different method for its isolation. White and White[5] and Arnow[6] confirmed the results of Kögl in a small number of experiments, but Dittmar[7], who followed Kögl's technique for the isolation of glutamic acid, failed to detect the *d*-form of this acid in proteins from the growing parts of different types of sarcoma, though he was able to establish racemization of glutamic acid in the proteins from necrotic malignant tissue.

I have isolated glutamic acid from normal and malignant tissues by the method described by Kögl, due notice being taken of the technical details stated in his second paper. The experimental results are summarized in the accompanying table. As seen from these data, partial racemization of glutamic acid has been observed in a few cases in malignant tumours. In the majority of the tumours, however, no 'unnatural' glutamic acid was present. The extent of the possible loss of the *d*-form in the course of the isolation procedure was ascertained in an experiment in which 100 mgm. racemic glutamic acid were added to the hydrolysate from 5 gm. of dry muscle proteins. From this material 670 mgm. glutamic acid were obtained, with an amino nitrogen content of 7·51 per cent and 27·5° specific rotation. Thus 42·8 mgm. have been recovered from the 50 mgm. of *d*-glutamic acid added to the muscle protein hydrolysate. Further, we have recrystallized from 20 per cent hydrochloric acid 200 mgm. of a glutamic acid mixture with $[\alpha]_D = +24°$ made from 150 mgm. *d*-acid and 50 mgm. of the racemate. Upon recrystallization we obtained 174 mgm. glutamic acid with $[\alpha]_D = +25°$. These values show that the percentage of *d*-form lost in the course of isolation and purification of glutamic acid from protein hydrolysates by Kögl's method is low.

Our experimental data justify the conclusion that the presence of *d*(−) glutamic acid in tumour proteins is not a regular phenomenon attending malignant growth. Our present aim is to investigate the causes of the presence of *d*-glutamic acid in the hydrolysates from certain tumours. The data at our disposal for the present give no reason to associate this phenomenon with bacterial activity in the necrotized parts of the tumours, as suggested by Dittmar.

RELEVANT to the discussion which has taken place recently between Chibnall[1] and Kögl and Erxleben[2,3] are some facts which I have accumulated in an analysis of gliadin. Kögl and Erxleben find that the glutamic acid derived from the proteins of malignant tissue is partially racemized and suggest that this might be a characteristic of such proteins. Chibnall found tumour proteins to contain the bulk of their glutamic acid in the ordinary active form with $[\alpha]_D + 31 \cdot 6°$ in 9 per cent hydrochloric acid, and he thought that any racemization was incidental to the methods employed in its isolation. The work described here indicates that a vegetable protein such as gliadin also contains part of its glutamic acid in a racemic form, and that it is probably a general characteristic of proteins and not of special significance for the proteins of tumours.

600 gm. air dry protein (91·6 gm. nitrogen) were hydrolysed for thirty-six hours with 30 per cent sulphuric acid, the acid removed with baryta, and the barium salts of the dicarboxylates precipitated by adding 3 vols. of 95 per cent alcohol. This precipitate was dissolved in dilute hydrochloric acid, freed from barium, and saturated with hydrochloric acid gas. Five crops of glutamic acid hydrochloride were precipitated, with characteristics as shown in the accompanying table.

It was thought that this might be the derivative obtained from *d*-*l*-glutamic acid and so a sample of *l*(+)-glutamic acid was racemized by boiling a 0·4 *M*. solution in normal caustic soda for 130 hours until the specific rotation was zero. The free amino-acid was isolated, but still yielded the 3 : 5 dinitrobenzoyl derivative m.p. 104°.

It is thus not 3 : 5 dinitrobenzoyl *d*-*l*-glutamic acid.

The free acid is only sparingly soluble in hot water, and its equivalent weight by titration against standard baryta is 144. The copper salt is easily soluble in water and it sets to a glass on evaporation. Its rate of ring closure at *p*H 4 to form pyrrolidone-carboxylic acid is almost identical with that of known glutamic acid. On oxidation with free hypochlorous acid it yields succinic acid. All these factors confirm the belief that it is a glutamic acid.

Samples of the 3 : 5 dinitrobenzoyl compounds, m.p.'s 104° and 203°, were next hydrolysed by heating in a sealed tube at 120° for eight hours. The specific rotations determined in micro-polarimeter tubes indicated that the 104° derivative yielded an amino-acid having $[\alpha]_D$ in 9 per cent hydrochloric acid + 13·5°; whereas the 203° derivative gave an amino-acid with $[\alpha]_D - 2°$. As the rotation observed was only $-0 \cdot 14°$ in a somewhat cloudy solution, it might well be that the solution was inactive.

4	7·0 gm.	202°	5·6 gm.	7·40	19·4	+ 24·0°	0·53	104°	38·1%
5	3·0 gm.	175°	2·4 gm.	7·45	19·3	+ 5·8°	0·23	203°	{51·6%
	Isolated in su	bsequent	fractions				19·31 gm.	104°	3·0%
			6·0 gm.				0·59 gm.N.	203°	58·0%

All five fractions were converted to 3 : 5 dinitrobenzoyl derivatives with the results indicated—the first four fractions yielding a derivative having m.p. 104°; the last crop a 203° m.p. derivative. Both derivatives analyse as for 3 : 5 dinitrobenzoyl glutamic acid, but the 104° derivative crystallizes with one molecule of water, whereas the 203° derivative is anhydrous.

The mother liquors from the precipitation of glutamic acid hydrochloride (4·4 gm. nitrogen) were reprecipitated with baryta and alcohol, giving a precipitate (2·34 gm. nitrogen) and a filtrate (2·02 gm. nitrogen of which 0·55 gm. nitrogen was present as NH_3). The precipitate was freed from barium, converted to copper salt to separate aspartic acid and then subjected to Dakin's treatment in order to see if any hydroxyglutamic acid was present. None was found, but the silver precipitate and the silver filtrate together yielded another 6 gm. of a glutamic acid which gave a 3 : 5 dinitrobenzoyl derivative, m.p. 203° (≡ 0·57 gm. nitrogen).

The copper aspartate which looked a homogeneous blue crystalline mass was also examined, and from it by crystallization there was obtained 2·35 gm. of glutamic acid and 2·25 gm. aspartic acid. It would thus appear as if the copper salt were a double salt of copper aspartate and copper glutamate (1 : 1), as the 4·86 gm. of amino-acid obtained from it would require to be in the ratio 2·55 gm. glutamic acid : 2·31 gm. aspartic acid. This glutamic acid also yielded a 3 : 5 dinitrobenzoyl derivative m.p. 203°.

There is thus the curious fact that the first four fractions of glutamic hydrochloride yield a 3 : 5 dinitrobenzoyl derivative which crystallizes with 1 H_2O and has m.p. 104°. Fraction 5, however, yields a derivative, crystallizing without water, m.p. 203°, and all the subsequent fractions yield the 203° m.p. derivative.

The amino-acids obtained by hydrolysis of the 3 : 5 dinitrobenzoyl compounds were re-benzoylated, and this time both yielded the derivative m.p. 203°.

It appears to me that the probable explanation of these facts is that the glutamic acid obtained by hydrolysis of the protein contains, besides *l*(+)-glutamic acid, some racemic glutamic acid; and as *d*-*l*-glutamic acid yields the derivative m.p. 104°, this racemic acid is probably not an artefact but a definite hydrolysis product. It is important to remember that this *d*-*l*-glutamic acid received violent treatment (boiling for 130 hours with normal sodium hydroxide) in comparison with that accorded to the natural glutamic acid. However, to complete the investigation a study of the equilibrium conditions for the reaction

$$d\text{-}l \text{ (mixt.)} \rightleftharpoons \text{racemic (compd.)}$$

is being undertaken both for glutamic acid itself and for its 3 : 5 dinitrobenzoyl derivatives.

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX

ANNUAL REPORT

THE Association of Special Libraries and Information Bureaux arranged to hold its sixteenth annual conference at University College, Nottingham, during September 15–18, 1939. Owing to the War, the meeting did not take place, but a report including the papers which were to have been presented together with the Council's report on the year's work of A.S.L.I.B. 1938–39 and a report of the fourteenth annual general meeting held on November 24, 1939, has now been issued*. The report indicates that the membership stands at 334 as against 325 in the previous year, and the financial position continues to restrict the activities of the Association. One hundred and eight translators are now registered, but this service is not nearly so widely used as it should be. At the annual meeting, the chairman emphasized that under war conditions the need for a clearing house for information is accentuated and the Council aims at keeping the work of the Association going as normally as possible.

Of particular interest to scientific workers are the papers dealing with "Thesis Literature" by Colonel Luxmoore Newcombe, of the National Central Library, Mr. Watson Davis and M. Julian Cain. Colonel Newcombe, dealing with the accessibility of British university thesis literature, emphasizes the need for more information about such theses, to which we have no adequate guide. The accessibility of theses for consultation or loan is discussed and some details are given of existing catalogues in university libraries and the collections of foreign theses in such libraries. Colonel Newcombe also discusses the feasibility of compiling and publishing a national guide to these theses, as well as the advisability of each university filing in its library two copies of each unpublished thesis accepted for any degree. The compilation of such a catalogue of unpublished theses in each university library, and the collection in one library, possibly the National Central Library, of copies of published foreign theses, which would be available for loan, also require consideration.

Mr. Watson Davis, in his paper dealing with the accessibility of the thesis literature of the United States, emphasizes the service which the American Documentation Institute is able to offer for obtaining American dissertations on microfilm in co-operation with the libraries and institutions concerned. M. Julian Cain's notes on thesis literature in France describe the centralization of such theses in the Library of the University of Paris (Sorbonne). A complete set is sent to each university library in France annually and to all foreign libraries participating in the exchange scheme.

A paper by G. S. Fulcher discusses the value of author's abstracts as an aid to documentation and advocates the extension of this system, preferably through some organization such as the International Federation of Documentation. Dr. L. A. Sayce contributes a paper on microphotography in 1939 in which he refers to the research work proceeding at King's College, Newcastle-on-Tyne, and the need for a central library, preferably in London, to take the lead in Britain by establishing a well-equipped micro-copying bureau.

Papers of more general interest are those in which Sir Harry Lindsay describes the work of the Imperial Institute as an information centre ; Mr. Guy Pocock describes the libraries and information bureau of the British Broadcasting Corporation, and Mr. Thomas Baird discusses the cinema and the information services, in which he emphasizes the important educational work the cinema could render in wartime conditions, notably in evacuation problems.

* Report of the Proceedings of the Sixteenth Conference, organized to be held at Nottingham University College, September 15th to 18th, 1939. Pp. 92. (London: A.S.L.I.B., 1939.) 5s.

LEVEL MEASUREMENT AND CONTROL

AN important class of instruments among those required for scientific purposes as well as for the many accurate measurements which are now an essential feature in industrial and engineering undertakings is that which is designed for indicating, recording and controlling liquid levels. Many devices have been adopted for these purposes, one being the employment of compressed air which is arranged to be slowly discharged through an open tube the end of which is submerged in the liquid. As the head of liquid above the open end varies, so does the pressure of air, thus giving an indication of the level. Instruments of this type are suitable for almost any fluid and give single or multi-point readings, or they may be adapted for continuous records. Where the provision or use of an air supply presents difficulty or is undesirable for special reasons, depth indicators and level recorders may be of the self-contained pressure bulb type. The bulb is installed at the zero of the level to be measured and is connected by tubing to the instrument, which may be at any desired height above or below the liquid and at any reasonable distance from it.

For tanks the mercury column can be conveniently employed, and a precision type of instrument based on this principle is capable of an overall accuracy of 0·005 of an inch of mercury. Instruments for level and depth alarm or control are of pneumatic or electrical types and, at maximum or minimum or both, they operate bells, klaxon horns or pilot lights to give warning or regulate a diaphragm control valve so as to maintain any desired level. The pneumatic principle can be applied also to measure the specific gravity of liquids of variable density by two standpipes connected to a differential pressure indicator or recorder. In a list recently issued, Messrs. Negretti and Zambra, who have wide experience in the manufacture of instruments of these types among many others, have supplemented the illustrations with accessory schedules and diagrams showing how the several models are employed and connected under different conditions of service. More than a catalogue, it is thus a handbook for the reference of those responsible for the selection and installation of level measuring instruments.

THE PUBLIC HEALTH IN WAR-TIME*

IN every war of which we have records the wastage from disease has outnumbered many times the losses from killed and wounded. Figures from the War of 1914–18 support this statement, as well as the experience of the Walcheren expedition and the Crimean campaign.

Military and civil authorities are both interested in the maintenance of the public health in war-time. Military and civilian health authorities successfully co-operated in this respect during the War of 1914–18, and similar arrangements have been made in the present war.

While indirect war consequences, such as alterations in diet, excess of work and worry and the pandemic of influenza (1918–19), contributed to increased rates of mortality among civilians in the War of 1914–18, the record of civil public health was good on the whole. The population increased and the infant mortality rate was lowered. It must be remembered that that War saw the beginnings of those personal health services which have done so much to improve the health of the community; for example, the School Medical Service (1907), the Insurance Medical Service (1912), the Tuberculosis, Maternity and Child Welfare and Venereal Disease Services. It is a harder task in the present War to maintain the health services at the high level they have reached. In addition, unprecedented demands have been made on the national health services. The central health authority has become a more important arm of defence, and has had to organize an emergency medical service, in itself a stupendous task, and an evacuation scheme for school children, expectant mothers young children and other priority classes of the population.

An account of the emergency medical service and of the medical problems of the evacuation scheme was also given.

Certain criticisms of the evacuation scheme were discussed. It was emphasized that the Public Health and School Medical Services should not be blamed for departures from the normal standards of cleanliness and conduct found in certain of the evacuees. The root cause of these conditions lies in the home. They mean that slum clearance has not yet gone far enough, that low standards of living still persist, and that the lessons taught in the school and clinic sometimes fail to reach the older generation.

It was suggested that the policy of preparing for casualties and of evacuation may have played no inconsiderable part in the present freedom of Great Britain from enemy air raids.

Reference was made to certain diseases—deficiency diseases, tuberculosis, venereal diseases, influenza, infectious diseases, cerebrospinal fever—which are the objects of special concern in this War. The civilian arm has yet to receive its baptism of fire. If that stern ordeal comes, it will endeavour to keep the flag of national health flying in the storm of war as zealously as it did in the sunshine of peace.

* Substance of a Chadwick Public Lecture delivered on February 20 by Sir Arthur MacNalty, K.C.B., Chief Medical Officer of the Ministry of Health.

HAULAGE PRECAUTIONS IN MINES

OF the deaths caused by haulage accidents in mines, the fact that over a period of eight years nearly 25 per cent were due to runaway tubs is sufficiently serious to indicate this as a subject demanding inquiry. One of the lines of research undertaken in this connexion was to determine the relative degree of effectiveness of the different types of backstay which are used as one means of arresting potential runaways. The backstay, which is known by several local names, is a strong steel bar which trails along the rail track at the rear of the string of tubs, its function being to dig into the track if the train tends to run back. Frequently its action is ineffective, and this led to one line of research being directed by the Department of Mines towards ascertaining the chief causes of the failures and the ways and means of preventing them by improving the design of this simple safeguard. The results of this investigation have now been published under the title "Backstays for use in Mines" (Safety in Mines Research Board Paper No. 103. H.M. Stationery Office. 1*s*. net). which describes all the steps taken and results obtained and makes available to the coal mining industry the conclusions reached.

Representative types of backstays having been obtained from several coalfields, these were examined for variations in design. They were classified in four groups, the classification mainly depending on the method of attachment to the tub. In other respects very marked differences were noted; length varied from 23 to 42 inches and weight from 9¾ to 72 lb. They were subjected to a number of tests under conditions simulating those which might actually occur when tubs are on an incline, such as allowing tubs to run back for some feet before the stay is free to operate, or being bumped into by a runaway. The results of the several tests are recorded in relation to the four different groups of the original classification. From these it was possible to draw conclusions as to a suitable mode of attachment, safe limits of length, weight and cross-section and general construction. It is interesting to note that the ideal length is about that of the longest stay examined and its weight should be about 40 lb.

The metallurgical and mechanical tests of the materials used in the sample stays showed that they have usually been made of soft steel and therefore have been relatively weak and easily bent. The report recommends that high quality steel should be used, preferably 1·5 per cent manganese steel as previously suggested for colliery haulage drawgear.

In addition to the details of the investigation, the paper gives the analysis of the problem in relation to different numbers of tubs on various inclines. The formulæ published should be of considerable assistance in checking the sizes required under any given conditions.

TRANSVERSE DISTRIBUTION OF HORMONES IN PLANTS

BY E. D. BRAIN

"THE relation between various types of hormone distribution is the internal regulating mechanism of a plant." This conception underlies the theory of the transverse reactions of plants which Georg Borgström discusses in a recent publication[1]. He emphasizes the physiological importance of transverse hormone distribution in relation to polar transport. Starting from the discovery that treatment with ethylene upset the normal transport of auxins and caused a transverse flow out of the phloem into the surrounding tissue with consequent swelling of the cells, Borgström studied various natural conditions which produced similar effects. He found that light of short wave-lengths, high humidity, high and low temperature, action of specific chemical substances, mechanical stimulation of the phloem and the age of the plant organ were factors which influenced the direction of auxin distribution, by diverting the normal polar stream into transverse channels with resulting reaction in the plant. Among these "transverse reactions" of the plant he classes tropistic growth responses, the light-growth reaction, secondary growth, root formation, root contraction, water transport, fruit development and leaf fall. He also discusses various other physiological and morphological problems in the light of his theory and suggests that the transverse distribution of hormones is responsible for various ecological types; the strength of the reaction being governed by the extent to which normal growth is upset by the transverse effect.

It is impossible to discuss here the numerous applications of the transverse theory, but I propose to deal with Borgström's interpretation of the mechanisms of photo- and geo-tropism, which is in some way illustrated by my own work on geotropism[2]. According to Borgström, light induces lateral hormone transport which increases the transverse growth of cells of the cortex and retards their elongation on the light side of the stem. Histological studies by various workers have endorsed this, and Borgström's measurements for cells of the cortex in Pisum stems and Lupinus and Helianthus hypocotyls, when submitted to unilateral illumination, show marked increase in width and decrease in length on the illuminated side. A transverse growth effect is therefore included in the mechanism of phototropic curvature. What has been termed as increased sensitivity in the dark can also be explained as the normal elongation proceeding without interference from transverse light effects. A study of geotropically curved stems shows increased width of cells on the lower side, accompanied by elongation due to the accumulated auxin from the transverse effect of gravity. In the root the same distribution takes place but, since auxin inhibits growth, the lower side is retarded and positive curvature results. In my investigations on the growth of plants for prolonged periods on a klinostat, I have found histological changes which indicate the resultant of processes which would normally produce curvature. In hypocotyls of *Lupinus albus*, marked increase in the radial walls of the cortical cells was noted, and in radicles, cells of the cortex were much shorter in longitudinal section but only slightly smaller in transverse section. It appears as if radial extension is the predominant factor in negative curvature of the stem, whereas in roots the inhibition is more in the longitudinal direction. Reaction of shoots and roots is different and it seems doubtful if the transverse effect can be so complete an explanation of positive geotropism as Borgström suggests.

Besides seedlings, flowers and leaves of *Narcissus pseudo-narcissus* and fronds of *Asplenium bulbiferum* were grown on the klinostat. In Narcissus flowers no bend in the receptacle occurs on the klinostat but, at the stage when the bud bends normally, changes occur in the outer layer of cells. The difference in length of the dorsal and ventral halves of curved flower stalks has been explained by Zollikofer[3] as being due to the unequal elastic pressure of the two halves, as a result of unequal growth hormone distribution. On the klinostat the normally unequal distribution would be equalized and alteration in the elastic pressure might result, causing the tangential stretching of cells which are compressed when bending occurs normally. It is significant that these changes coincide with a maximum development of statoliths in the receptacle, which points to the possibility of some link between the statolith apparatus and the bending mechanism.

In Narcissus leaves the epidermal cells are shorter and there is a greater number of stomates on both the inner and outer surfaces of the leaves grown on the klinostat. The cells of the cortex of *Asplenium bulbiferum* fronds are much wider radially and shorter on the klinostat than in upright plants. On the klinostat there is less sclerenchyma formed. The walls of the sclerenchymatous cells are much thinner and the cells are half as long and more than twice as wide as in upright fronds. Heyn[4] has shown that geotropic stimulus causes changes in the plasticity of cell walls as a result of auxin redistribution. In this case the continual transverse auxin supply prevents the cells ageing and losing their plasticity, and the formation of sclerenchyma is retarded. In all cases examined, no difference was found in the distribution of starch and statoliths in plants on the klinostat. Borgström questions the idea of the statolith mechanism and geotropic reaction being causally related. He considers that it is the transverse distribution of auxin caused by gravity which increases the mobility of the starch grains and facilitates their falling, at the same time inducing differential growth of longitudinal and transverse cell walls. From experiments with onion and oat roots he shows that auxin activates diastatic processes and accelerates the transformation of starch into sugar, and he assumes that it is a transverse distribution of auxin which causes the disappearance of starch from developing tissues, making sugar available for growth purposes. Should this be so, one would expect to find that an artificially induced transverse distribution would change the distribution of starch in klinostat plants.

It is clear that a change in the direction of auxin distribution may alter the plasticity of cell walls and lead to definite changes in plant tissues. The possible applications of this theory offer wide scope to the research worker in many problems of plant physiology and morphology.

THE SCATTERING OF WAVES IN RADIO TRANSMISSION

FOR many years past, the mode of propagation of radio waves through the ionosphere has been studied intensively by mathematicians, physicists and radio communication engineers. It is now well known that all long-distance communication takes place by deflection of the waves in one or other of the ionized regions of the atmosphere, and furthermore that, depending upon the density of ionization of any particular region, there is a maximum frequency of the waves which will be deflected and above which the waves penetrate the region and are not returned to the earth. This critical penetration frequency increases with the angle of incidence of the waves on the ionosphere. Thus, while the general features of long-distance radio transmission can be interpreted in terms of a simple ray treatment of the waves passing from the earth up to the ionosphere and back to the earth, there is a minimum distance from the sending station at which signals can be received by this mode of propagation. This 'skip' zone or distance, as it is termed, is naturally subject to diurnal and seasonal variations, as well as to the actual frequency used in the transmission.

Although all normal commercial communication takes place by the transmission of waves to ranges beyond the skip zone, it has been known for some time that, inside this zone, signals may be received more or less spasmodically, these signals being very irregular and subject to large variations in both intensity and direction of arrival at the receiving station. This type of reception has been interpreted as being due to the scattering of waves from local irregular portions or clouds in the ionosphere, where the intensity of ionization is such as to give rise to a diffuse reflection of the waves in all directions.

In a paper read before the Wireless Section of the Institution of Electrical Engineers on February 7, Mr. T. L. Eckersley presented an analysis of the effect of scattering in radio transmission. The earliest experimental evidence of scattering was obtained from observations at Chelmsford in 1927, when the short-wave beam stations were first opened. In general, such scattered signals within the skip zone gave no definite bearing indication on a direction-finder unless the sending aerial emitted a directive beam, in which case the apparent direction of travel of the waves was approximately the opposite to that in which the beam of rays was projected. In later work, it has been possible to measure the time delay of the scattered signals in relation to the ground or direct ray, and also in some instances to the normal echoes received after one or two reflections from the *F* region of the ionosphere. The scattered echoes are of relatively low intensity and thus only become suitable for quantitative observation when a high-power transmitter is available, and the use of a pulse modulation makes possible the measurement of the time of arrival of the individual echoes.

Photographic records demonstrated by Mr. Eckersley showed that the scattered echoes have a moderately well-defined minimum time of arrival, but beyond this, the received echoes are spread over a considerable period in an irregular manner. A complete investigation of the phenomena showed that the cause of such scattering lies in momentary irregularities and small clouds in the *E* region of the ionosphere. Since the wave frequencies employed were generally much greater than the critical frequency of the *E* region, the path of transmission from the sender involved penetration of this region, reflection at the higher *F* region, followed by scattering from the upper side of the *E* region, and so by a second reflection from the *F* region back to the receiving station on the ground. The time delays of the echoes fits in with this explanation, and the fact that the average intensity of the scattered signals varies approximately as the fourth power of the wave-length is in accordance with the scattering coefficient of ionic clouds in the *E* region.

The effect of scattering is of major importance in the analysis of long-distance radio transmission phenomena, and the results of the investigation described in the paper referred to do much to increase our knowledge of the subject and our understanding of the mechanism by which the scattering is produced.

SEVENTY YEARS AGO

Nature, vol. 1, February 24, 1870

The Minister of Public Instruction

Reference is made in a leading article to the Education Bill, the first reading of which was taken in the House of Commons "last week". The reception given to the Bill suggests that a Minister of Public Instruction will shortly be appointed.

"Such a Minister should, we think, take charge of the whole range of natural knowledge in all matters in which the State in any way intervenes to advance such knowledge. We understand the comprehensive term natural knowledge to include Education, Science, the Fine Arts, and Music. . . . The Education branch would include the national system of compulsory primary education about to be established, public schools, universities. . . . The Science branch would include all establishments, in receipt of Government assistance, in which Science is taught as a special study; all those in which scientific observations or investigations are conducted under State auspices, and all museums in which natural objects are displayed for scientific purposes. . . . The first step towards organizing this branch of knowledge must be by collecting facts and opinions relating to it. This step can only be taken through the agency of a Royal Commission instructed to give the widest possible scope to its inquiries into everything relating to both Instruction and Investigation in Science."

"A deputation consisting of Earl Fortescue, the Right Hon. C. B. Adderley, Dr. Farr and others, had an interview with Mr. Shaw-Lefevre at the Board of Trade on Saturday to recommend the legislation of metric weights and measures in the Post Office, and the legal substitution of metric weights for the troy weight which the Standard Commissioners propose to abolish."

"We have to record the decease of Mr. J. F. Sowerby, so well-known in connection with the illustration of botanical works, especially the new edition of the English Flora, edited by Mr. J. Boswell-Syme, now nearly completed."

"A method of protecting iron from atmospheric influences has been proposed by Messrs. Macmillan and Macgregor, of Dumbarton and Glasgow. They bring melted sulphur into contact with the cold metallic surface to be coated. The sulphur chills and sets into a hard, thin, protecting cover."

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Resident Headmistress of the Royal Masonic School for Girls, Rickmansworth Park—The Secretary, Royal Masonic Institution for Girls, 31 Great Queen Street, Kingsway, W.C.2 (March 1).

Chief Chemical Inspector, Chemical Inspection Department, Royal Arsenal, Woolwich—The Ministry of Supply (S.E.3.B.), The Adelphi, W.C.2 (quoting Appts. 021/S.E.3.B.) (March 4).

Lecturer in Bacteriology, Royal Veterinary College, and Research Assistant in the Research Institute in Animal Pathology—The Bursar, Royal Veterinary College, The University, Reading (March 9).

Headmistress of the County School for Girls, Gravesend—W. A. Clench, Bank Chambers, Windmill Street, Gravesend (March 11).

Professor of Mechanical Engineering—The Secretary, The University, Birmingham (April 20).

Part-time Teacher in Chemistry—The Head of the Department of Chemistry and Biology, The Polytechnic, Regent Street, W.1.

Civilian Wireless Instructors at the Electrical and Wireless Schools, Royal Air Force—The Under-Secretary of State (S.5.D.), Air Ministry, Adastral House, Kingsway, W.C.2.

Assistant Mechanical Engineers for the Electrical Branch, Public Works Department of the Government of Nigeria—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9067).

Mechanical and Electrical Engineer for the Public Works Department of the Government of the Gold Coast—The Crown Agents for the Colonies, 4 Millbank, S.W.1 (quoting M/9120).

Two Assistant Engineers—The Engineer, Nene Catchment Board, Priestgate, Peterborough.

Temporary Forecasters, Grade II (Male) in the Meteorological Office—The Under-Secretary of State, S.2.B.(Met.), Department Q.A., Air Ministry, Adastral House, Kingsway, W.C.2.

Headmaster of the Sydney Grammar School, Sydney, New South Wales—The Agent-General for New South Wales, 125 Strand, W.C.2, or The Secretary to the Trustees, Sydney Grammar School, Sydney.

THE UNIVERSITIES IN WAR-TIME

THE function of the universities in relation to research needs in war-time may not be so well appreciated as other factors which at the present time are directing attention to their place in the national life of Great Britain. Like other educational institutions, their work has in many places been seriously disturbed by the exigencies of evacuation. Both research and teaching have been interrupted, and even where satisfactory and efficient arrangements have been made in the reception areas for the performance of those functions, great difficulties have frequently been met by students. These difficulties, for example, have deprived University College, London, and the London School of Economics of half their students. Although a number of evacuated university institutions are now expected to return to their normal quarters by the autumn term, there is sound reason in the appeal of the National Union of Students for a Government grant to enable students who would otherwise be deprived of their education to continue their studies.

The attempt to return to normal education and to evolve a sound and practical policy out of the muddle into which evacuation has thrown it must include university education along with the elementary and secondary stages. In contrast to 1914, the universities have indeed already been recognized by Government as institutions of national importance, both from the point of view of assisting in the War, and also of maintaining higher learning and culture. The welcome news that the Government has decided to maintain its Treasury grant at the pre-War level (see NATURE, February 24, p. 299), strengthens this conviction. In the contacts of the past year or so between the universities and the Service and other Government departments in regard to the utilization of personnel and facilities, and particularly in the sympathy and understanding which characterize this co-operation, we have evidence that the role of the universities in supplying the educated and trained leadership essential in handling the problems of a democratic society is fully appreciated by the Government.

If therefore it is admitted that universities are vital necessities in the efficient service of the needs of a democratic society, whether as an industrial nation in a world where science is the basis of power, or in the defence of its life, its liberties and traditions against the methods of modern warfare, it can scarcely be disputed that a grave responsibility must rest on the universities in the preservation of the permanent values of our ordinary life. The autonomy of government, the freedom of speech and thought and investigation which are cherished privileges of British universities, place upon them a prime responsibility to provide the informed and disciplined intelligence that alone can be adequate to meet the needs of a post-War world, to repair the breaches made in our institutions by the War, and to reconstruct those parts of our political and economic system which are shown to be defective by the War. If reconstruction is to have a practical meaning, it requires at once the trained and disciplined intelligence, the impartial and patient analysis, the imaginative insight on human issues, the sense of values and creative force which it should be a chief glory of our universities to supply.

The importance of the contribution which the universities can make to the winning of the War, to the planning of the peace and the provision of leadership of the requisite capacity, makes it essential that the ways and means by which that contribution is made should be rigorously re-examined. It is no simple problem to secure the economy that may justly be demanded, without endangering the deeper values which a university must always safeguard. The Treasury grants to the universities have always recognized the right of the universities to enjoy complete freedom. In war-time, that independence must be preserved at all costs. Nothing is easier than for the essential liberties for which we are contending to be endangered and lost by gradual encroachment under the duress of war.

Unsleeping vigilance in these matters is essential, but the universities must prove themselves worthy of that independence by the thoroughness of their response to the national need, and the ability with which they not only maintain their highest traditions but also raise the efficiency of their service. On the economic side there are things with which they can do without, and without which they will be content. They will not expect the same funds for new buildings which in better times they ought to have. It is not in war-time that we can expect most of our modern universities to approach nearer to the Platonic ideal that youth should be brought up "amid fair sights and sounds".

The essentials of university education must not be stinted. Municipal bodies, like the State, should continue their help at least undiminished, increasing it where those essentials are lackingor inadequately provided. Even in war-time, it is a good investment for the nation to provide at the modern universities more opportunities for healthy recreation as a part of the corporate life. The Physical Education Centre which the University of Manchester has recently opened is a token of the movement to make the life of the modern university more rounded and complete. Behind that movement, moreover, lies the possibility of developing a system of physical education which will make the student's life happier and more efficient in the best sense ; and there is a large field for research, the knowledge garnered from which may be applied not only to university students but also to adolescents generally.

Here is only one of the directions in which the universities might, even in war-time, extend their services to the community. There is also a great task in extra-mural work, which some of them are already shouldering, despite all the handicaps imposed by the black-out. Programmes of lectures are being provided for troops in the areas served by the universities in an attempt to see that the minds of those called to the colours do not stagnate or become set in Service grooves. In spite, too, of the dislocation of civil life and the long hours put in on munitions, the demand for tutorial classes is strong, and the teaching normally done outside the universities on their own initiative or in collaboration with the Workers' Educational Association proceeds vigorously.

The significance of this extra-mural work should not be under-rated. As Dr. W. C. Mitchell reminds us in his presidential address to the American Association for the Advancement of Science (see NATURE of February 10, p. 207) the gravest dangers to democracy come from within, not from without. The universities have a decisive part to play in dispelling ignorance and countering by critical inquiry the propaganda which turns ignorance to its uses. In war as in peace, those who cherish learning must seek to foster, by all means within their power, a scientific attitude among their fellow citizens. Extra-mural work offers an invaluable opportunity of developing respect for evidence and promoting a general understanding of the methods and results of science.

Important as may be the educational functions of the universities in such extra-mural fields, it is to the training given within their walls and to their functions in the advancement of knowledge and the maintenance of standards that attention is at present being most clearly directed. The pursuit of knowledge and the training of youth must indeed go hand in hand with the cherishing of human values—of personality, of freedom and truth—if a university is to make its full contribution to the enrichment of national life, above all by inspiring that deep consciousness and appreciation of the national heritage which alone can sustain the effort and sacrifices which their defence may well demand in the present struggle. Whatever resources may be available for the universities—and the importance of their contribution to our war effort and the preservation of the permanent values of our heritage may well justify expansion rather than contraction of those resources—the present position demands that they should be used as wisely and efficiently as possible.

It is from this point of view that it is imperative to re-examine the utilization of these resources and their distribution over the various functions of a university and the numerous branches of learning which it serves. Let no one imagine that this is a simple task. The complexity of the relations between the different functions and faculties must not deter us from the task, and the gravity of the danger which threatens all alike may well be sufficient at last to initiate the effort.

In regard to the advancement of learning, the university occupies a place in the research front. If knowledge is to be available to serve the war-time needs of the nation no less than to solve the problems of peace, some means must be found of keeping an appropriate balance between fundamental and applied research, of providing for the following-up of advances in knowledge, and of diverting effort to fields neglected or holding up the general advance. All this must be done without endangering that freedom of investigation and spirit of unprejudiced quest for truth which lie at the root of all scientific advance. Particularly is it important to provide for investigations in the domain of human relations, where lack of knowledge is already handicapping our war effort in many fields.

The advancement of knowledge links itself naturally with the teaching functions of the university through the thorny problem of the relation of teaching and research. Here we may well have to review the whole question of technique in the light of recent criticism and discussion on the use of the lecture or the tutorial system. Similarly, we have to consider the efficiency of research at the universities, not merely in terms of the claims of teaching, tutorial or administrative duties, but also in regard to the provision of adequate assistance or services in the laboratories, so that the best use is made of the time of qualified research workers.

These are questions which, like those of professional training, may well occupy the attention of the universities themselves and also of the many professional associations of scientific workers and their fellows. We cannot expect in the stress and strain of war to find and apply a completely satisfactory solution to them all. We may indeed need to be content with eliminating major causes of inefficiency and securing a modicum of co-operation in the pursuit of knowledge where it is most required. If, however, scientific and professional workers, whether within the walls of a university or without, are zealous enough in cherishing a high ideal of the functions of a university and give their minds, even in war-time, to such problems as these, then at least we may be sure that the universities of Great Britain will carry undimmed through these dark days their power to inspire, and to provide the loyal and unselfish leaders the nation needs both now and in the days of reconstruction to come.

CANCER: THE ROLE OF SURGERY, RADIUM AND X-RAYS IN ITS TREATMENT

THE treatment of cancer has occupied an increasingly important position in public thought during the last few years. The debate in Parliament on the Cancer Bill laid bare the scanty provisions for adequate treatment existing in many parts of Britain. The war crisis in September which temporarily curtailed medical facilities resulted in an insistent demand for the treatment of cancer, a demand not immediately heard for the treatment of most other diseases. One aspect of this interest is the difference of opinion as to the proper scope of radium treatment relative to other methods, a difference illustrated by recent and present correspondence in NATURE (**144**, 973; 1939; **145**, 151; 1940; also p. 347 of this issue).

Before attempting an assessment of the present status of cancer treatment, it will be instructive to examine first the extent to which cancer is in fact being treated in Great Britain at the present time, and the means available. A recent Ministry of Health inquiry* showed that in a representative sample 27 per cent of all cases were actually treated by either surgery or radiation, including purely palliative treatment. Allowing for possible groups of cases not coming into the sample, it is safe to say that less than 30 per cent of all cases occurring receive treatment. As to the means available, there are only two by which successful cure of cancer can be achieved—surgical excision and radium or X-ray therapy.

*"Cancer: An Enquiry into the Extent to which Patients receive Treatment." Reports on Public Health and Medical Subjects, No. 89 (H.M. Stationery Office.)

Surgery was first in the field, and indeed was for many years the only available method of treatment. The principle underlying its use is simplicity itself; extensive removal of the growth along with the whole of the affected part. The effective use of surgery in cancer dates back to about half a century ago. At that time surgical techniques were evolved which are still known by the names of their creators—Halstead, Kocher, Wertheim, and many more. The surgery of cancer is now relatively stable; its accomplishments are known, its limitations accepted.

In contrast to surgery, radium and X-ray therapy are still young and developing branches of medical science. Although radium was discovered in 1898 and was applied to minor medical use shortly afterwards, it did not become an important means of treating cancer until after the War of 1914–18. In the decade 1920–1930 the significance of the work which was being done in three now famous radiation therapy centres—the Fondation Curie in Paris, the Radiumhemmet in Stockholm, and the Memorial Hospital in New York—was gradually realized. It was not, however, until about the end of that decade that the impact of these revolutionary methods became generally felt. In Great Britain one result was the establishment of the Radium Trust and the creation of the National Radium Commission Centres for the provision of efficient radium treatment. It is then no overstatement to say that this new medical specialty is a mere ten years old, and still in an evolutionary phase. This fact has three consequences. In the first place, it is only over a very limited field of use that methods of treatment are as yet sufficiently standardized to represent an established practice of modern medicine. In the second place, it is vital that its value be judged in terms of its capacity as known to-day, and not in terms of its accomplishments of even a brief five years ago. Thirdly, it holds considerable promise for the future.

To arrive at an objective analysis of the relative value of surgery and radiation it is worth while first to examine the nature of the 27 per cent of treated cases mentioned above. The striking fact which emerges from such a study is that treatment is limited to a comparatively small number of cancer types. Of the 27 per cent of all cases occurring which in fact received treatment, no less than three-quarters belonged to one or other of the following five cancer groups: cancers of the stomach, intestine and rectum; cancer of the breast; cancer of the skin, including genitalia; cancers of the mouth, tongue and lip; cancers of the uterus and vagina.

Cancer of the stomach, intestine and rectum constitutes almost exactly 400 out of every 1,000 cancer deaths and represents one of the very commonest types of cancer found. In view of this, it is depressing to find that only 8 per cent of this group are seen sufficiently early to permit an attempt at cure. The treatment is almost exclusively surgical and radiation is as yet of little value. A generous estimate of the percentage cured would be 15 per cent of cases treated.

Cancer of the breast constitutes 200 cases per 1,000 of all cancer deaths occurring in women. It was found to have been treated in 68 per cent of cases. Breast cancer undoubtedly represents the field in which surgery has accomplished its greatest victories. It is still the treatment of choice except in those cases which are inoperable when first seen. In these, radiation does provide a useful alternative method. In many cases both surgery and X-ray therapy are combined with great advantage. A fair estimate of the surgical cure-rate is 25–30 per cent of all cases operated on. In the really early cases a cure rate of up to 75 per cent can be obtained. Cancer of the breast should be looked upon, therefore, as a mainly surgical field.

Carcinoma of the skin represents only a small proportion of all the cases occurring. It can be treated by wide surgical excision, or it can be treated by radiation—either radium or X-rays—with equal or even greater certainty of cure and without the same degree of disfigurement; indeed, often such a return to normal occurs that the site from which the disease was eradicated cannot be distinguished. An estimate of the cure-rate of true skin cancer (squamous cell carcinoma), adequately treated by either method, may be given as about 75 per cent. The less serious form of skin cancer, known as rodent ulcer, if treated properly rarely proves fatal. This field is therefore one which can be equally called surgical or radiological, but the cosmetic advantage lies with radiotherapy.

Cancer of the mouth constitutes just under 100 cases per 1,000 of all cases occurring in men, and analysis showed that 71 per cent were treated. There is little doubt now that radiation, particularly radium, has become the treatment of choice in this disease. The majority of mouth cancers occur in parts where surgery is not practicable. Where excision is possible, for example, in some carcinomas of the tongue, surgical cure is infrequent and is attended with marked disability. Extension of the disease from the mouth to the glands in the neck may, however, be dealt with either surgically or radiologically. Many cases of mouth cancer come for treatment when the disease is already advanced, yet even so cure-rates of 25–30 per cent for all the cases treated have been reported by British radiation therapy centres. For the early case, the chance of cure is at least 50 per cent. The mainstay of treatment of mouth cancer must therefore be accepted as being radium therapy.

Cancer of the uterus (uterine cervix) represents 133 cases per 1,000 deaths from cancer in women. Before the days of radiation it was treated surgically. This has now been abandoned in all modern schools. The present situation has been described in a recent survey where it is stated that "radiation offers a prognosis some 10 per cent better plus an appreciable salvage of inoperable cases. . . . To-day the prognosis from good radiation therapy is a one in two chance of cure in an operable case, and a one in seven chance in an inoperable case, and in selected centres the prognosis is even better, the chances being two in three and one in four respectively". The rapid transition from surgical to radiation treatment is largely due to the statistical findings of the Health Section of the League of Nations. This disease can therefore be listed as an exclusively radiation field.

These five diseases together account for 75 per cent of the treated cases. The remainder include cancers of the lung, œsophagus, bladder, ovary, larynx and a large variety of less common lesions. Talking in general terms, treatment by surgery and by radiation is probably about equally common, and radiation is showing curative possibilities in a number of lesions which are impossible of surgical approach.

We see, therefore, that in three out of the five main curable types of cancer considered, radiation now occupies a place so generally accepted that patients treated otherwise cannot be considered as receiving the maximum chance of cure.

The value of radium and X-ray therapy is, however, not limited to the treatment of forms of cancer in which permanent cure is possible. It can serve two other quite important functions. In a wide group of malignant growths, which include the lympho-sarcomata, radiation can control the disease and maintain the patient in a fair state of health for long periods. Another way in which radiation is extensively used is to obtain palliation of advanced cancers where cure is impossible. These cancers include the late stages of all those types which are curable in the early stages by radiation or surgery and many more. The growth of the tumour can be arrested temporarily, with disappearance of the attendant pain and disability. Even although life is only prolonged for a short time the reduction in suffering is great. Surgery has contributed two useful measures to the palliation of cancer—gastrostomy and colostomy. Both these measures, by affording mechanical relief in incurable cases, prolong life and reduce suffering.

Much has been written on the dangers of radiation treatment, as in the past of the dangers of surgical treatment. Where the disease concerned is cancer, in which the mortality of untreated cases is 100 per cent, danger should obviously not be overstressed. In surgical techniques a certain 'operative mortality' is regarded as inevitable. In the use of radiation for the cure of cancer similar 'treatment risk' must be faced. In both surgery and radiotherapy this risk varies in direct ratio to the magnitude of the undertaking and in inverse ratio to the skill of the operator or therapist. While the immediate risk of death is lower with radiation treatment, a new risk has to be taken, namely, that of local necrosis due to the treatment. At times this is unavoidable, and necroses may be faced at the time of treatment as being the price of what is regarded as curative treatment. Such necroses can be repaired later by plastic surgery.

The nature of the action of radiation on malignant tissue is a totally different process from that of excision, and radiation should not be thought of as a refined form of cautery. While surgery seeks the eradication of the disease by wide excision, radiation has a selective action on malignant cells in those groups of cases where the radiotherapist claims success. In the epitheliomata and the sensitive sarcomata it is possible to give a dose of radiation which will destroy the malignant cells while doing only temporary harm to the surrounding normal tissues. The margin between lethal dosage to the malignant cell and the lethal dose of the normal tissue is, however, quite a narrow one. To permit the successful use of this differential sensitivity an expert training in radiotherapy is necessary, both to assess a suitable dosage and to choose the best means of delivering that dosage accurately to the tumour with a minimal radiation of healthy tissue.

Radiation has occasionally been stated to produce metastases and to 'stimulate' the growth of malignant cells. Neither of these statements can be substantiated.

In the development of radiotherapy a vast amount of experimental work is still necessary. At present the techniques employed are based on clinical experience, which is necessarily conservative. The choice, for example, of radium versus X-rays depends on the mechanical applicability of either to any particular lesion rather than on any known advantage of wave-length. In accessible sites it is usual to choose radium, which remains the more valuable of the two methods. X-rays are used in the radiation of deep-seated lesions and in widening the zone of tissue treated from a radium source.

Another factor which requires investigation is the optimum overall time of radiation. At present the times used depend on clinical experience, and it is felt that other overall times or time splittings of dosage may be found in the experimental field which will alter considerably our methods of treatment.

While stressing the need for developmental work in radiation methods and the value of surgery and radiation in their respective fields, it is necessary to state that the greatest increase in the cure-rate in these fields would be obtained by a successful campaign to get patients in the early stage of their disease. A well-planned scheme of public education and clinics as envisaged in the Cancer Bill would facilitate this.

RUTHERFORD

Rutherford
Being the Life and Letters of the Rt. Hon. Lord Rutherford, O.M. By Dr. A. S. Eve. Pp. xvi+451+18 plates. (Cambridge: At the University Press, 1939.) 21*s.* net.

PROF. EVE'S account of the life of his old friend Lord Rutherford treats it in the perfectly straightforward manner which such a book should. He takes the reader steadily through the life from boyhood in New Zealand to the 1851 Exhibition at Cambridge, the chair at Montreal, the chair at Manchester, and the return to Cambridge. A great part of the history is given through the medium of Rutherford's letters, many of the earlier ones being those written to his future wife.

The order of presentation is rather strictly chronological, so that successive paragraphs may deal with entirely different subjects; for example, they may consist in accounts of a public lecture, a holiday journey, the organization of a department, and a new scientific discovery. In describing the purely scientific work, Prof. Eve at intervals devotes a few pages to a non-technical explanation of its import, which should help the inexpert reader in understanding the steady progress of the discoveries in which Rutherford took the leading part. In fact the biography is cast mainly in the form of a chronicle, and this is exactly the form it should have. There will remain for some later historian, who will have gained the perspective and impartiality of time, the task of assessing the respective merits of the enormous contributions that Rutherford made to physics. Taken in conjunction with his published books and papers, the present biography will provide very complete documentation for such a historian, and it should go a long way towards protecting Rutherford from the two dangers to which the lives of the great seem to be specially exposed, on one side the degeneration into a dreary hagiography, and on the other the psychological account of the (usually Freudian) thoughts which the biographer thinks that his subject ought to have been thinking.

With a biography, as with a portrait, the author is always faced with an almost insuperable difficulty, that of satisfying both those who knew the subject and those who did not. The first expect to be reminded at every turn of the living original, whereas the others, with no personal memories, have to build the whole image out of the author's own work. So it is natural to ask whether Prof. Eve has 'got it across'. He has certainly given himself the best chance of doing so by his copious quotations from the letters. These, be it said, are mostly quite ordinary letters, dealing with the happenings of Rutherford's life, such as those written to his family when on a visit to America, or those to friends on the Continent renewing relations after the War of 1914–18. They are good straightforward descriptions of events, not embellished into anything like belles-lettres—had they been so one would have doubted their authorship—and anyone can feel that he *could almost* have written them himself. But not quite, for there is a tremendous common sense about them and a vigour raised to high power, which is the characteristic that his intimates will most remember. But in reading them the intimates will have in mind the associated memories of the general raciness of his conversation, of his amusing reminiscences and the critical but usually kindly comments on his contemporaries. This side of him is very much harder to describe in a biography, because it can only be done by illustrations of a topical kind, and the mere attempt to give them would destroy the lightness which is their essence. It is a matter for briefer treatment than is possible in a book, and we may hope that, before memories fade, there will be gathered together a Rutherford saga, of the kind of which a beginning was made by Tizard's lecture last spring. There are many men, great to their friends but little known to the world, of whom the same sort of thing is true, and usually their memory does not long survive. But here the greatness was combined with an external greatness patent to the world at large. May we not hope that this will just make the difference and lead to the survival of the whole man.

It is impossible to read the life without trying to estimate what the verdict of the distant future will be of Rutherford's various discoveries. Many of them, which in another man would be counted as of the very first class, can be attributed to accurate timing on his part. Rutherford himself used to say, in connexion with some of the wilder speculations of his contemporaries, that no one could see more than an eighth of an inch beyond his nose, and that only a great man could do even that. He had himself just that extra little range of sight beyond the eighth that got him there ahead of the rest. One cannot doubt, for example, that the law of radioactive decay would have been explained by someone else, if Rutherford had not done it a few months earlier. In other cases he got the lead by his capacity for choosing the right one among several confusing alternatives, by his gift for always "picking the right bottle off the shelf". Thus one distinguished man of science would write to him reporting a new type of radiation, and he would be entirely unmoved, correctly attributing the result to some unconsidered impurity, while another would write a very similar letter and he would stop all the other work of the laboratory and Chadwick would discover the neutron.

In the case of some of his discoveries, however, Rutherford was much more than a few months ahead of his competitors. For example, the study of α-particle scattering was undertaken in order to probe into the atom, and the ordinary scattering by electrons did serve to give at least a strong suggestion that the number of electrons was about half the atomic weight; the scattering of a few particles through broad angles was an unforeseen extra gift. It is one of those profitless but interesting speculations to conjecture what would have happened if Geiger had failed to detect those particles, or if, as it would have been almost natural to do, he had explained them away. The nucleus would have had to wait; but for how long ? Atomic number would have been discovered, but it would have been through Moseley's spectra and it would have been only a curious numerical rule unsupported by any theory. Would Bohr have made his theory of the hydrogen spectrum, without the guiding principle that there was a centre of force attracting according to the inverse square ? Probably, but it might have been somewhat later, and the theory, suspect to the orthodox even as it was, would have had a much more difficult passage. After that there would still have been the experiments on collision to repeat, and so it seems likely that Rutherford found the nucleus at least three or four years before anyone else would have done it.

In the discovery of atomic disintegration he was probably even farther ahead of his contemporaries, and he owed this largely to his breadth in insisting on developing technical methods and exploring whole fields, where smaller men are content to solve single problems one at a time. This wisdom went much farther still, for at an age when most men are entirely set in their habits, he showed that he could recognize that his old simple methods were becoming inadequate for the new knowledge, and that he must—and that he could—embark on the elaborate engineering feats of the modern physical laboratory.

The discoveries of the present epoch can be divided into two types, for which a very good discrimination is according to whether Rutherford liked them or not ; the difference can be felt, but it is hard to put it into words in any other way. The nucleus and disintegration were his own, and he foretold the neutron and was in at its birth. He liked Bohr's theory of atomic structure, and accepted the new quantum theory though without much enthusiasm ; perhaps this was because for a time it put the theorists above the experimenters. At any rate, he could welcome Gamow's theory of radioactive change, and Mott's work on the interference of α-particles with helium atoms. But the positron was not to his taste ; of course he accepted it, but the very abstract idea of 'holes' did not fit his habit of thought. Would he have liked the meson ? Probably not. But the most recent discovery of all, the fission of uranium into comparable parts, that would surely have been a discovery which, had he been spared for little more than a year longer, would have been one of the most acceptable to his genius.

C. G. DARWIN.

ELECTRIC CLOCKS

Electrical Timekeeping

By F. Hope-Jones. Pp. xx + 275 + 6 plates. (London: N. A. G. Press, Ltd., 1940.) 10*s.* net.

SOME few years ago, Mr. Hope-Jones brought out his well-known book "Electric Clocks", and I had the privilege which I much enjoyed of writing a notice of it, which appeared in NATURE of October 17, 1931. I am very glad to be enabled again to notice a new book—"Electric Timekeeping"—by the same author. I say a new book because the title is a little different. I think it should be called a new and enlarged edition. "Electric Clocks" came out when it had become generally recognized that the Shortt clock had revolutionized our ideas as to the possible attainable accuracy of pendulum clocks, and when for the first time the uncertainty had been brought down to a matter of a second in a year. There was then full justification for the author, who had himself invented many of the features on which success depended, adopting the role of the high priest and laying down the law as to what is good and what is bad. As anyone who has seen the first would expect, the present work does not falter in this respect.

The author, who has devoted himself to the subject of accurate clock construction for nearly half a century, is so saturated with the subject, and is so familiar with the almost innumerable ways in which the electric current has been harnessed as an aid, that his presentation of the history of the development is almost bewildering in its thoroughness, but there is this which makes his treatment of real value. It is not a mere catalogue of a thousand-and-one devices in chronological order, but a very critical discussion of each showing the valuable original steps which, however, lacked something necessary for real success, or the essential faults in principle which were so common.

In the earlier volume the author led up to what might well be called the perfect clock—or very nearly perfect clock—the Shortt clock. In the present volume the history is mainly a repetition, but much has happened since "Electric Clocks" appeared. The quartz crystal clock, though it had proved its value so long ago as the year 1928, had not then become so well known as it is now, or perhaps had not reached the present high level of performance, which is, I believe, an uncertainty in the rate of one second in two or three years. In 1928, comparisons of Mr. Marrison's quartz clock in New York connected by land line with Mr. Loomis's three Shortt clocks at Tuxedo demonstrated the disturbance of gravity by the moon. Then again the time laid on by the alternating current network in the country, though known as a possible source of accurate time, had not become general as it now is; and in this, by the way, the author appears to have been the first to point out the possibility*. Again, time at sea, which used to be altered daily by the captain when he said "make it so", is now beginning to pass at a variable rate made to fit the easting or westing of a ship on a plan also proposed by the author. These, the Post Office "Tim", and many other things are discussed in the additional matter.

The author may well be pleased to have had the support of the late and of the present Astronomer Royal. These two great authorities have written the forewords to the two volumes, and this is a distinction of which he may well be proud. He is also able to exhibit a frontispiece which itself is an attraction. When crossing the Atlantic to attend a meeting of the Franklin Institute, where he was presented with the much-prized Gold Medal for his share in the development of the Shortt clock, by rare good fortune Einstein was on board. The frontispiece is a 'snap' of the two in earnest conversation autographed by Einstein himself.

It is now nearly fifty years since the author developed that admirable production the synchronome clock, which was a well-deserved success. Relying on the principles which he never tires of preaching, he invented element by element that invaluable instrument. I must mention in particular two of these. The first is the step-by-step dial ratchet which never fails. This is figured on p. 103. It may seem a small thing, but it represents a degree of perfection unknown before. It has the great merit of not being upset even if the ratchet wheel is eccentric or badly divided. The other is the synchronome switch which applies a gravity impulse to the pendulum every thirty seconds. This contains an element of the first importance, a contact which is a really forcible one, that itself transmits the power to lift the gravity arm and thereby lasts only so long as is necessary. This saves battery waste, provides a sharp time signal, and it never fails.

The triumph of the Shortt clock, which after all is based on the synchronome clock, has not caused the author to rest on his laurels. The latter part of the book records one after another of his further inventions. One is a method of synchronizing a light half-second's pendulum depending solely on circular error. This is a beautiful device, and if the synchronizing current is first set for every second it very soon starts from rest and is in proper phase.

---

* "Lightning", November 15, 1895.

Another and much less expected invention, if indeed any invention by the author relating to clocks can be considered unexpected, is an alternate current motor of great ingenuity and value. Two microscopic motors of a few mouse-power had hitherto almost monopolized the field. One was the high-speed self-starter, the Warren motor, which can only go one way, and the other the toothed disk lower speed motor, which is not self-starting and which will go either way. Some few weeks ago a public clock was seen to be going backwards and this led to a crowd wondering, I suppose, how long it would be before it would become yesterday again. This might have been due to the man who started it turning the twiddle nob the wrong way. But the author again comes in with an extra slow-speed toothed wheel motor turning once a second with a permanent magnet for the stator. This, he says, is more efficient than the others, which it may well be. I have used the others in other apparatus and determined the mouse-power of each, which was surprisingly large. I should much like to have one of these new motors on which to experiment.

These are only a few of the author's later achievements. They are all so neat and so practical that it is with regret that I am compelled by consideration of space alone to leave them unmentioned.
